As I read through the positions of the various countries, I found that the predictions of the ITU hams had been, if anything, far too optimistic. Virtually every country proposed serious cuts in the ham bands . . . some in favor of shortwave broadcasting, some for mobile services, some for short range commercial services, etc. For example, the Wireless Institute of Australia is one of the world's more vocal ham groups, with considerable strength in their country . . . yet the official position of Australia was to cut all ham bands down to 50 kHz width!

If that sounds drastic, our good Asian friends in India officially proposed that all ham bands be cut to 20 kHz – worldwide – and they seemed to have a good deal of support from several smaller countries.

The mood of the hams at Geneva was glum. True, the official U.S. position was to back the present ham allocations and ask for no changes. But when I took the other delegates on the U.S. team out to breakfast, lunch, dinner, coffee, etc., I found that in virtually all cases, their confidential instructions were to reflect any losses to their service to the nearest ham band. In other words, if they lost 50 kHz of allocation, it would be taken from a ham band to give them back the lost 50 kHz. This is how the 14,350 to 14,400 segment of 20 meters was lost in 1947.

The more foreign delegates I talked with, the more the conference looked like it would turn out to be a slaughter for amateur radio. Budlong was there, but he was asleep much of the time. Huntoon was all tied up with entertaining visiting ARRL dignitaries and acting as secretary for a few committees.

The U.S. strategy was to try to get all frequency allocations in the 3-30 MHz segment postponed until the next ITU general meeting, scheduled for around 1969. This would pull the fat out of the fire on a lot of the shortwave allocations where the U.S. had a disproportionate share. The U.S.

Title Your Pix With A Micro

-- a useful SSTV accessory

Upon the successful completion of my SSTV picture generator program[1], I decided my next logical applications program would be one to title SSTV pictures. This project was selected since a majority of the programming was already written and debugged in my previous project. To accomplish this task, another piece of equipment was required. This piece of equipment is an SSTV scan converter. This equipment is quite interesting because it takes normal TV from a fast scan camera and converts it directly to SSTV. Since the TV is digitized in the process, it is quite easy to mix computer-generated video with the camera video.

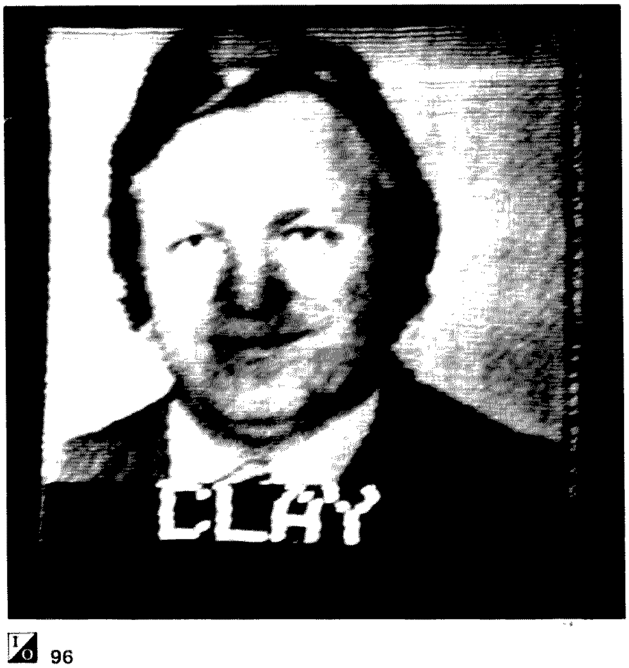
Prior to any system layout or programming, I decided upon a few ground rules which would affect the total project. These rules were:

1. The entire program must be coresident in the SWTPC memory with my SSTV generator program in 8K memory.
2. Little or no hardware interface would be required.
3. An MXV 200 Scan Converter would be used to generate the SSTV.[2]

The selection of the MXV 200 Scan Converter was an obvious one — I had one in the shack. But even beyond that, it is the only scan converter available with pins on the main connector to pick up sync pulses and locations to mix the digital video. Other units could be adapted to this application (e.g., the Robot 400[3]).

As with my previous programming projects, the first steps required were to determine detailed programming specifications and then to draw flowcharts. Additionally, I decided to use a structured programming approach and modularize the program for ease in writing, debugging and making future changes.

For anyone attempting such a project, this is an absolute necessity. As a result of these steps, I had the program totally operational in three weeks. Try and accomplish the same project in hardware logic design in such a time frame! This point demonstrates how powerful microprocessors are, and how easily the SWTPC 6800 System can be programmed.



MXV 200 Scan Converter

A fast scan camera is connected directly to the unit as shown in Fig. 1. The first stage is used to shape the signal, and, in the second stage, the sync pulses are stripped from the fast scan video. The fast scan sync pulses are used to clock the 1K shift register memory and to generate the slow scan sync. The shift register memory is then loaded at a slow scan rate into a digital-to-analog converter and then into a slow scan modulator. The important concept which is required for the whole thing to work is to slave the microprocessor to the scan converter. This was accomplished by attaching the horizontal and vertical sync signals to the SWTPC 6800 Peripheral Interface Adapter (PIA) input port (pins 1 and 2). The output from the SWTPC 6800 was taken from two pins of the output PIA port (pins 4 and 5). Two pins were required for output, one for background and the other for character dots. The whole setup is shown in Fig. 2.

The Software

The programming routines

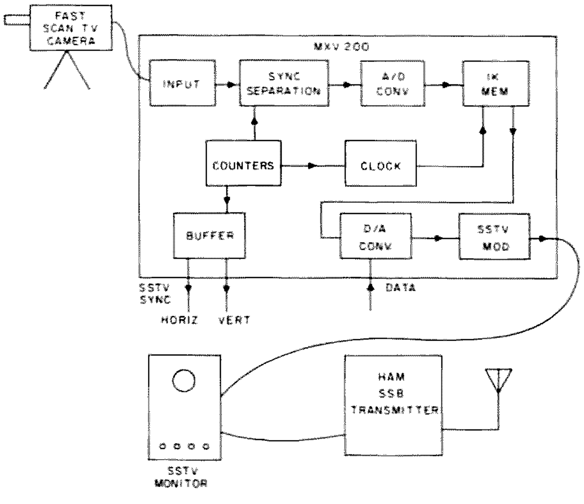


Fig. 1. MXV 200 Scan Converter block diagram.

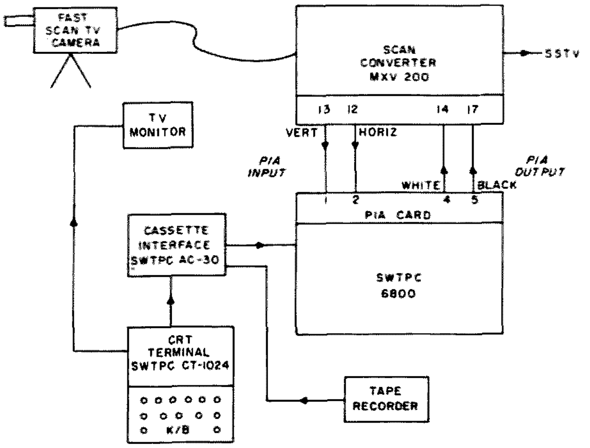

Fig. 2. Scan converter/computer interface.

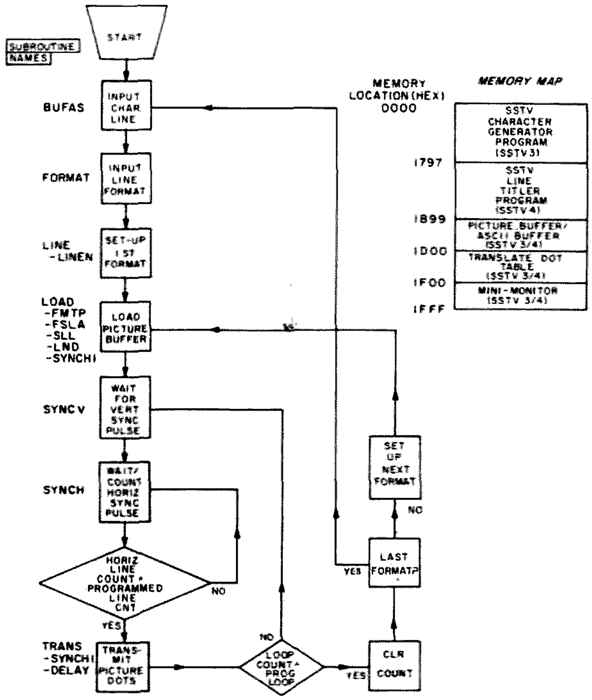

Fig. 3. Main line program.

used to generate the picture dots are similar to those used in my previous article. Therefore I will not discuss them in this article.

However, I will discuss the algorithms I used for picture sync and other significant changes. I will first start by listing a few of the features of the titler program.

1. The titler program mixes up to 10 lines of SWTPC 6800 generated characters with SSTV scan converter generated pictures.
2. The SWTPC 6800 computer connects directly to the MXV 200 and Robot 400 without a hardware interface.
3. Ten different titles can be stored in the SWTPC 6800 System's memory.
4. Titler program can place 1 line of 9 SSTV characters on any one of 9 locations of the SSTV picture.
5. Titler program can mix up to ten different formats which consist of picture loop/number/line.
6. Program includes a mini-monitor which allows the user to select the titler or generator program.
7. The mini-monitor allows the user to select either 50 or 60 Hz SSTV with the generator program.
8. The mini-monitor allows the user to select either white characters on a black background or black characters on a white background.

Fig. 3 shows the main line flow of the titler program along with the subroutine names and a memory map. The SYNCV and SYNCH subroutines are two of the most important routines and function as follows:

1. The program senses the PIA, bit 1 or 2, and waits for it to go positive.
2. When the pulse goes positive, the program then waits for the bit to go to ground and then branches out of the routine.

As you can see, all that is now required is to count the horizontal sync pulses and, when the preprogrammed value matches the actual count, a line of slow scan characters are inserted into an SSTV picture.

The TRANS subroutine functions like the SSTV generator program. Fig. 4 contains a flowchart of this routine along with the memory counter locations used for storage of the various program constants.

The loading of the picture dots is similar to the generator program with one major exception — the picture dots are loaded immediately after the transmission of a titler line or prior to the start of the program. These are convenient times to perform operations of this type, since the computer would only be waiting for sync pulses.

Fig. 5 shows how the character dots are loaded into the picture dot buffer. The picture buffer consists of 126

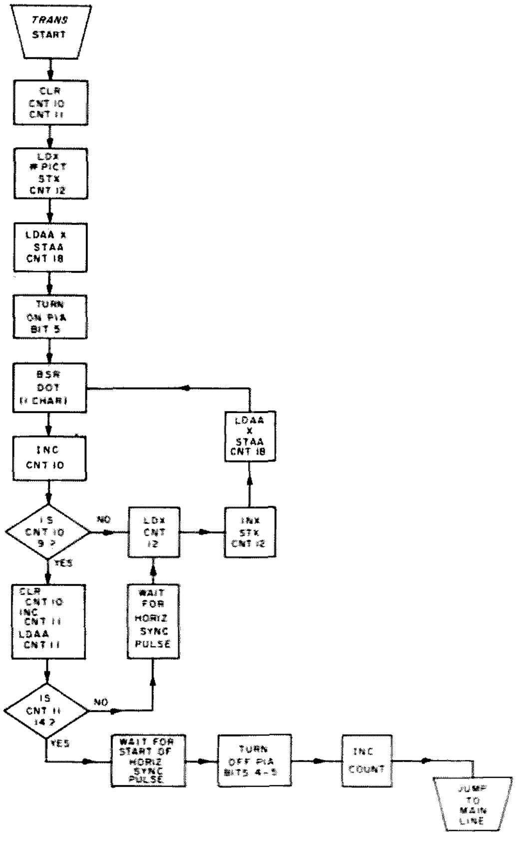

Fig. 4. Transmit picture line of 9 characters. COUNT = actual count of numbers of transmits. CNT 18 = temp. byte storage for picture dots. CNT 10 = character count. CNT 11 = Number of horizontal scan lines transmitted. CNT 12 = temp. storage for index register. PICT = address of picture dots in memory.

SSTV TITLER PROGRAM

Program A. Object listings for SSTV titler program.

bytes of data formatted as shown in Table 1.

Each of the 9 bytes of picture data is duplicated for each scan line. Since the characters were formed by a 5 x 7 dot matrix, the total number of scan lines is 2 x 7 = 14, and the total number of bytes is 9 x 14 = 126. The picture dots are loaded from the same dot and translate table contained in the generator program. This table is also listed for ease in program entry (see Program A).

Well, you now have a good idea of how the program works. Let's discuss how to use the program.

Operating The Program

After you load the program into memory, you should first set locations A048 and A049 to the start address of the program 1F00. When you type G, the TV monitor screen will be filled with a menu of the program options. If you plan to also use the generator program with the mini-monitor, one programming change should be made at locations 0355-6. The address of 0000 should be changed to 1F000. This will cause the generator program to branch back to the mini-monitor program after the characters are transmitted.

When the titler program is first executed, a menu will appear on the TV screen which will allow you to select a few program options. Photo 1 shows the mini-monitor menu. A brief description of each option follows:

1. Transmit SSTV. This option will cause the program to jump to the character generator program. If the previous change was made (address 355), the program would return to the mini-monitor when completed.
2. Title SSTV. This option selects the titler program. When the option is completed, control will be returned to the mini-monitor.
3. 60 or 50 Hz SSTV. This option modifies the program delay constants in the generator program at location 02E3.
4. Black on white titles. When selected, this option will place black letters on a white background. Four program constants are changed in the titler program. This is the normal condition when the program is first loaded. Normally character data is on PIA bit 4 and background is on bit 5.
5. White on black titles. When selected, this routine produces white letters on a black background in the titler program. The same four program constants are changed, character data is now on bit 5, and background is on bit 4.

Let's assume that you have selected the titler program option. The first instructions

you see on the screen are shown in Photo 2. This routine is asking for an entry into the ASCII buffers of 9 characters. Ten buffers can be loaded (0-9). When you place an ASCII letter under the letter B, the program will then jump to the next routine.

The next routine is shown in Photo 3. This routine sets up the picture titles to be placed on the SSTV screen. The entry is formatted by the program in the order LOOP/PICTURE/LINE.

Up to ten of the above formats can be entered and the whole process will be terminated at the end of the tenth format, or when an ASCII letter is typed.

The following is a description of each format term:

1. Loop entry. Reply should be 1 to 9. This entry controls the number of SSTV frames which will contain the picture title you select. If you reply with a zero, 255 loops will be assumed. In order to recover from this condition, you must put a 00 in COUNT at location 1AAD, or wait for 34 minutes of SSTV (255 frames).
2. Picture entry. This number corresponds to the picture buffer previously loaded. The reply should be 0 to 9.
3. Line entry. This reply selects the SSTV scan line at which the title will start. The reply should be 1 to 9. The following is a list of reply versus scan line:

Line no.	Scan Line
0 or 1	1
2	15
3	25
4	39
5	53
6	71
7	85
8	105
9	113

This concludes the description of how to use the program. Next, we'll discuss how to interface the SWTPC 6800 to the scan converters.

Interface Considerations

As I stated earlier, the

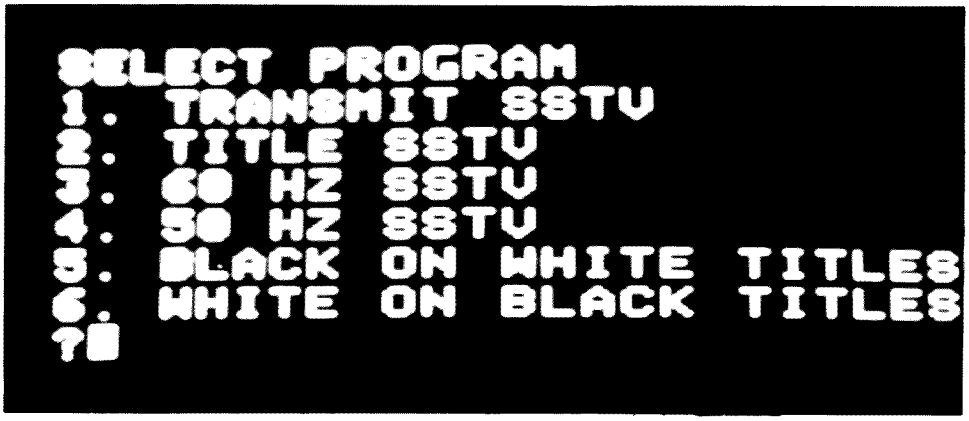

Photo 1. Mini-monitor routines.

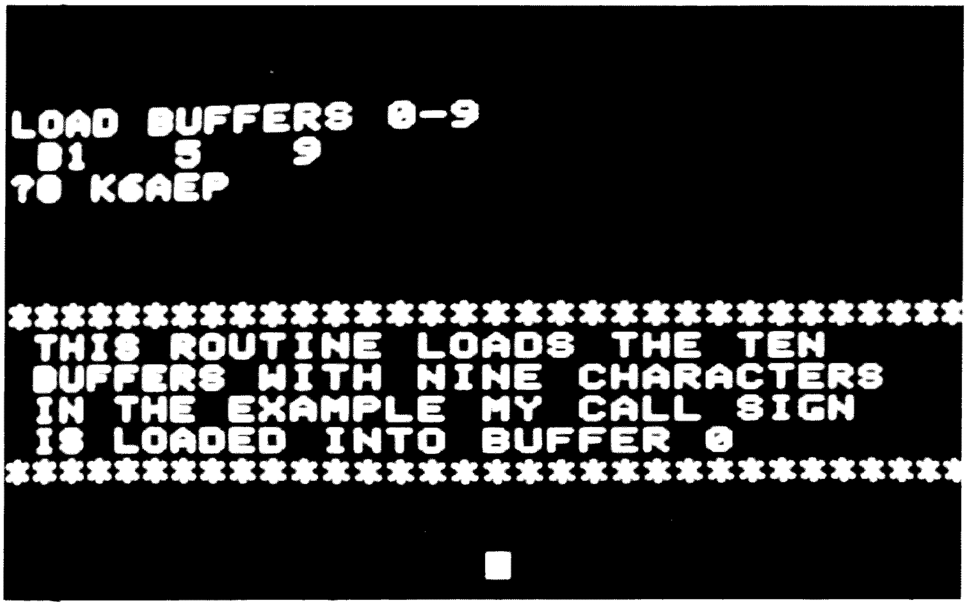

Photo 2. Titler program option.

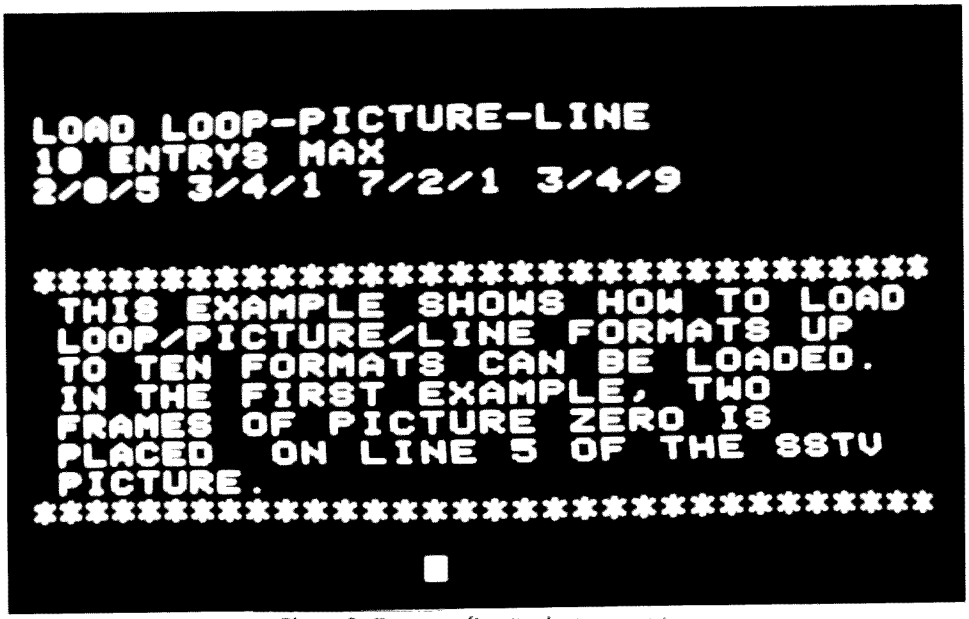

Photo 3. Entering (loading) picture titles.

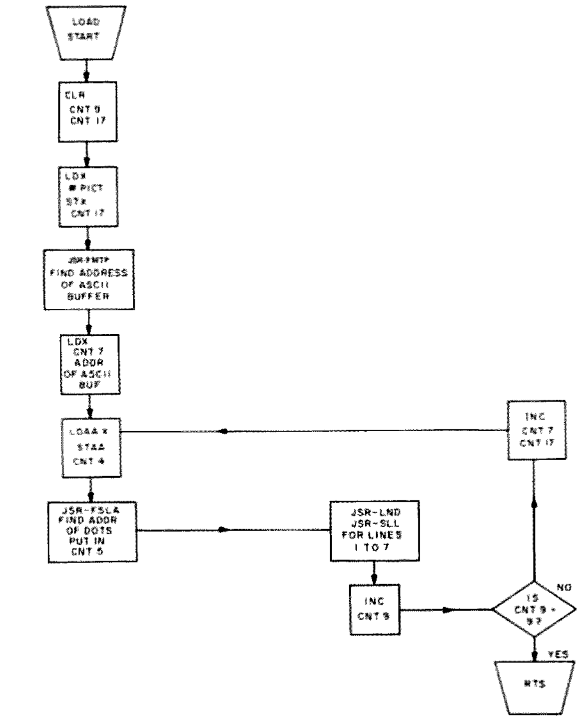

Fig. 5. Load character dots in picture. Memory counters: CNT 4 = ASCII character byte. CNT 5 = address of picture dots. CNT 7 = address of ASCII buffer. CNT 9 = character count. CNT 17 = address in picture buffer for dots.

Character Position (bytes)

location									
1B9A	1	2	3	4	5	6	7	8	9
1BA3	1	2	3	4	5	6	7	8	9

Table 1.

Unit	Signal	PIA Bit	Location
MXV 200	Vert Sync	input 1	pin 13
	Horiz Sync	input 2	pin 12
	White Cont	output 4	pin 14
	Black Cont	output 5	pin 17
Robot 400	Vert Sync	input 1	U44 pin 1
	Horiz Sync	input 2	U44 pin 2
	White Cont	output 4	U54 pin 1
	Black Cont	output 5	memory rev switch (S1)

Table 2.

MXV 200 is the easiest unit to interface to since all the correct signals are on the main connector. Table 2 lists the interconnection to both scan converters mentioned earlier.

The Robot 400 interface requires some additional comments from those listed in Table 2. The white control is obtained by removing U54 (74LS175) from its socket and bending pin 1 up. When installed on the board, a fine wire, #30, should be connected to a free pin on the main connector and then interfaced to the computer. The black control is not available on the circuit board. However, pin 5 of S1 (memory reverse switch) can be used. Remove the wire from +5 volts on pin 5 of switch S1 and connect PIA bit 5 to it through a spare pin on the main connector. You may have to experiment somewhat in this area since I do not have a Robot 400 to attach to. You may have to experiment with the program constants to achieve the correct picture polarity. The program constants are located at locations 1BØD, 1B1B, and 1B29. These constants will have to be changed also in the mini-monitor.

If you decide to write about any questions, please include a self-addressed stamped envelope for my return answer.

This completes the functional description, operation and computer interface. I think a few words should be said regarding the SWTPC computer in general. The titler program assumes that MIKBUG is used and the following routines are used: E1D1 – Output one ASCII character; E1AC – Input one ASCII character; EØ7E – Output a character string.

Other system requirements are:

1. The output PIA address is side A at location 7, address 801C.
2. The input PIA is side B address 801E. Prior to execution of the program, the PIA is initialized by the mini-monitor. If the user does not use the mini-monitor, the PIA must be conditioned in a similar manner for the PIA to function properly.
3. The SWTPC 6800 must have at least 8K of memory.

I would like to thank Mike Tallent W6MXV for his technical guidance with this project. Additionally, I would like to thank Clarence Munsey K6IV for his help in providing data on the interfacing to the Robot 400. ■

Mastering Network Operations

-- everything you need to know!

Across the amateur bands there are many nets . . . the rag chewers net, the old-timers net, YL net, and a host of others too numerous to describe. Some of these "networks" have an official purpose; others may exist for club activities or just friendly chitchat. It is through this article that I hope to open some eyes, so to speak, into network operations, especially for those who misuse our net frequencies and/or have little understanding of the system. Many newcomers don't understand the networks as related to amateur radio, so it seems appropriate to begin by answering a frequently asked question:

What Is a Network?

Start by imagining a large circle which represents all amateurs on a certain frequency. A point in the center of this circle is the control station. This station asks for check-ins from hams within the circle and logs them, stating whether they have traffic or are standing by. One by one he takes in call letters, and each station checked in establishes a tie or a communication bond with the net control. You can see that after a while a large net will form, which is actually many stations tied to a central point, or the control station.

But what some hams don't understand is how important nets can be to the amateur fraternity. Take, for instance, military servicemen overseas who want to communicate with their loved ones back home. Without amateur nets, finding a particular city might be a long, tedious job. The same applies to maritime mobiles, aeronautical mobiles, and persons with urgent medical or priority traffic who may very well have short time limits.

Unless you're very lucky, finding a certain area may take hours, even with a crowded band! Going through a network can cut that down to just a few minutes.

How, Then, Can I Get Involved In Net Operations?

Becoming an active part of a network is not hard. The best place to start might be either the maritime mobile net or the intercontinental traffic net which meet every day on 14.313 MHz. Come there and you can count on good advice about network operations from a real down to business net. Just listen for a while. Then, when you feel you're ready, jump in head first.

But That's the Easy Part!

Order is needed for the proper functioning of a network. It would be absurd to operate without a control station or rules. Networks need not only members and traffic to handle, but also the smoothness and order that rules and regulations provide.

There are too many guys that leave cooperation up to the control. They figure, "Oh well, it's his job to keep order." Ridiculous, isn't it? On that basis, the net control spends half his time screaming for quiet so the net can operate. If you hear someone using improper procedures or causing interference, why not move him off frequency and politely explain the rules to him?

So, you see, being a net member means more than checking in every once in a while and handling traffic. Each member should realize the purpose of the net and accordingly try to keep and enforce the rules. FCC chairman Richard Wiley told me in a recent interview that he considers amateurs "self-policing." On the average, I'm sure that's true. But the networks on 14.313 can be a pretty poor example of this! Just tune in some afternoon and grab an earful of unmodulated carriers, endless chains of CQs, and ear-splitting splatter from stations on nearby frequencies. You'll be lucky to hear the net control . . . and not only that, but the net control will be lucky to hear you!

On that note, I would like to present a network "primer for misunderstood procedures" which, I hope, will help get the garbage off the nets.

Checking In

Sounds simple, doesn't it? The misuse of this maneuver is so incredible it might even qualify for a round or two in Ripley's.

Very basically, the check-in is a method used to enter a net. But before you rush right into a network, take the time to listen a few minutes. This enables you to catch up with the control and follow what he is doing. Then if you wish to check in, listen for the controller's signal. He'll call for check-ins when the way is clear for more stations. Do not take it upon yourself to check in. It only interferes with the process of handling traffic. Also, there may be special check-in calls, such as, "Check-ins, maritime mobiles only!" This means the controller only wants check-ins from maritime mobiles and for all others to stand by.

After waiting for the controller's signal, quickly and clearly give him your callsign, always remembering to keep it short and sweet. The control has no time to listen to inane chatter (such as your name, what the weather is like, your rig, and so on).

After you transmit your callsign, the control will respond in some way or another. If no response is given, wait again for a check-in signal and try once more. Depending on your output power and location with respect to the net control, it may take several tries before he acknowledges. In any case, the control usually responds by repeating your callsign and then either asking for further check-ins or telling you to "call your traffic" right away. When you're asked to call your traffic, don't rattle on! Just simply let the controller know who or where you wish to communicate with. (If you have no traffic, just say you're standing by.) Control may now do any one of a number of things. For example, WB4EZM checks in and is looking for Los Angeles. Net control may tell him to call Los Angeles, or do the calling himself. If there is a Los Angeles station already on frequency, control will hook WB4EZM and L.A.

together, and they will decide what frequency to move to. Suppose there is no Los Angeles station on the frequency. Then control will ask WB4EZM if he would like to have his traffic listed. If the reply is "yes," then WB4EZM remains on frequency in hopes that L.A. will come up soon. If the reply is "no," then the traffic is scratched from the controller's list and WB4EZM goes elsewhere.

Checking into a net is one of the easiest things in the world. But some guys don't get the picture.

In fact, the only person on a net to use the term "check-in" should be the controller, with the exception of stations with life-and-death, priority, or short-time traffic. But for most cases, don't call us, baby, we'll call you!!!

The Contact

Another one of those simple but misunderstood terms. Contact means that your station is on frequency and you would like to contact him. For instance, WB4EZM tunes into the net and hears Los Angeles check in and stand by on the frequency. At a convenient break in the controller's transmissions, WB4EZM says "contact," and he is hooked up with L.A. accordingly. Remember: Use "contact" only when you know for sure that the station you want is on frequency. Some hams use "contact" as a means of getting into a net, because the controller will usually respond to it immediately. They'll call for a station that isn't there and then say, "Oh, well, I thought I heard him!" This practice is unfair, and now many net controls will refuse to list these stations.

The Recheck

Not many problems with this one. It means, "I have moved off frequency with a station and contact was not established." In this case, the net control would ask you to call your station again and, if you receive no reply, give you the option of waiting on the frequency in case he returns or another station in the same area pops up. Losing a station could have been caused by heavy QRM, QRN, or otherwise nasty band conditions. So, you see, a net not only provides a method of linking stations, but also a way of re-linking them if they don't hook up.

The Checkback

Easy to understand, but consistently confused with the recheck. Checkback means, "I have moved off frequency with a station. Contact was established, the traffic passed, and I would now like to check back into the network." The misuse of this term is pure laziness. Recheck is used for checkback, and vice versa, which leads the net control off track. Understanding net language is a necessity!

The Check-out

Rarely used, but nevertheless existent. Looking at it tells you the meaning: simply, "I wanna get the heck outa here." Although a polite way of leaving a net, its rare use stems from it almost being a time-waster. As a net control, I can honestly say that the absence of this term hasn't hampered operations. If you're not there, you're not there!

Relays

Without relay stations, efficiency would be greatly reduced. At the QTH here in northern Virginia, I am totally unable to copy ones, twos, some threes, a few fours, eights, and nines. Skip conditions just won't allow it on 20 meters during the daylight hours. Therefore, I need stations to pick up those I cannot copy . . . relay stations. For example, I would use a station in Florida to receive traffic from up north and pass it along to me. Networks require the cooperation and patience of all their members to coordinate relay activities. But that isn't the only use for relays. Many times a station will try to break the net because he cannot hear the net control.

If you hear someone needing a relay, you can be the one to help. First, make sure the net control can hear you. You'll know whether or not he can from previous conversations. Next, ask the breaking station to stand by. Then at an appropriate break in the controller's transmissions, transmit "relay." If control acknowledges, he will tell you to pick up the traffic from the station unable to copy him. One word of warning: Many net controllers will refuse to list stations who break the net and are able to copy control.

Courtesy To the Net Control

A controller has an incredible chore coordinating some 50 to 100 (or more) stations. And the only reward is the satisfaction of running a good, smooth net. Efficient operation requires the help of all members. Don't leave it all up to the control. Here are some good guidelines to follow:

1. Politely ask all stations operating in the immediate vicinity of the net frequency to move elsewhere. If someone won't move, don't get nasty about it, just leave them be, and eventually they'll go away.
2. Aid the net control as a relay station, whenever possible.
3. Follow net procedures to the letter, and explain the rules to those who don't.
4. Become active! Use that phone patch where it is most needed!

The Three Cs

Well, here it is! The grand finale, and maybe you've already guessed my point. It's called the three Cs of network operation:

1. Courtesy – Always be courteous to the net control,

fellow members, and everyone else in the amateur society. Where does everyone else fit in? Just take a look . . . when you ask a station to move away from the net frequency, do it politely! Don't give the attitude that the nets want to take over everything within 5 kHz of the net frequency. Simply explain that the net needs breathing room to operate properly. Networks are a service, not a burden.

2. Cooperation – Try to get along well with the controller and follow the rules. If you check into a net, say you're standing by and mention you have a phone patch. The net control could throw anything your way! Be prepared to help out in any way possible, whether it's acting as a relay or handling traffic.

3. Commitment – Commit yourself to a net. It doesn't have to be every day. It can even be once a week! Nets need stations to handle traffic. Wouldn't it be great if you could check into a net, ask for a particular city or state, and hook up immediately? This is entirely possible if more people who have the time would at least monitor the nets for possible traffic!

I certainly hope you won't take this article lightly. Get in there! Find a net! Do your part! Here's a good way to get started:

The Maritime Mobile Service Net
14.313 kHz (20 meters)
7 days a week, starting around 1700 GMT.

The Intercontinental Traffic Net
14.313 kHz (20 meters)
7 days a week, with two operation times:
1. Morning – from band opening to around noon. Eastern time.
2. Evening – following maritime mobile net and continuing to band closing.

Note: Sometimes the IC net will not operate on Sundays. ■

Try A Trapped Dipole

-- save copper and coax!

Often the need arises for a permanent low cost antenna. A dipole or inverted vee is a good choice. They are easy to install and cheap to build. One of the disadvantages of such antennas is that they are only usable on a single band, unless they are fed with an open feedline and an antenna tuner.

Most traps used in amateur radio multiband antennas are made of a lumped inductance and capacitance in parallel. I tried to overcome this.

By placing a trap 32 feet 6 inches from the feedpoint, a current maximum will occur at 7200 kHz. With the correct wire length on the outside end of the trap, the antenna can also show current maximum at the feedpoint for 3900 kHz. In both cases, the dipole functions as a halfwave dipole.

Why not add another antenna under the existing 80 and 40 meter wire, fed at the same feedpoint, with another trap tuned for 21300 kHz? An outside wire of the correct length will give current maximum on 80, 40, 20 and 15 meters, all functioning as a halfwave dipole.

With the help of my XYL, I came up with this antenna. The information for construction follows. I hope it will do as well for you as mine does for me!

The dimensions given here are resonant at 3.9 MHz, 7.2 MHz, 14.3 MHz and 21.3 MHz. For 40 meters it's 160 turns, for 15 meters, 55 turns. Number 12 magnet wire is wound on a 1/2 inch rod, close wound. The coil is removed from the 1/2 inch rod and placed inside the 1/2 inch PVC pipe.

The PVC pipe is cut to 18 inches for 40 meters, 10 inches for 15 meters. The PVC is then placed inside the 7/8 inch ID, 1 inch OD aluminum tube. The aluminum is cut to 16-1/2 inches for 40 meters, 8-1/2 inches for 15 meters.

Drill a hole in the center (ends) of eight 1/2 inch PVC caps, and mount stainless steel eye bolts on them. (Cut off the eye bolts as short as possible, so they will not go into the PVC tube.) Now drill a hole to fit the #12 magnet wire below the eye bolt in each end cap. See Fig. 4.

Cement one end cap onto the PVC tube after bringing the end of the coil wire through the small hole. Secure a tin solder lug on one end of the aluminum tube, as shown in Fig. 3, with a pop rivet or small screw. Do not use aluminum or copper for the solder lug. Slide the aluminum tube over the PVC with the solder lug end first, and solder a jumper from the lug to the coil wire as close to the PVC cap as possible.

You are now ready to tune the traps. The traps were adjusted to frequency through the use of a grid-dip meter (checking on a receiver for accuracy). The coil can be changed quite easily if an extra turn or two is put on for adjusting purposes. The coil can also be wound with spacing and compressed or extended to get the traps exactly on frequency. Tune to 7.2 on 40 meters. Tune to 21.3 on 15 meters.

After the tuning is completed, the end cap can be cemented on. The two wires sticking out of the end caps are to be soldered to the antenna wires.

My antenna is supported in the center about 32 feet high and 10 feet at the ends. I show an swr of 1.2 to 1 on 3.9, 1.3 to 1 on 7.2, 1.3 to 1 on 14.3 and 1.2 to 1 on 21.3. The CW bands can be worked with the swr less than 2 to 1 on all CW bands.

The overall length is 106 feet, and it can be installed as an inverted vee in a lot less than 90 feet. ■

Parts List

PVC cement
8 1/2" PVC caps
56" of 1/2" PVC pipe
1 balun, 1:1
4 ceramic insulators
135' of antenna wire
50" of 1" aluminum tubing (a discarded lawn chair will do)
80' of #12 magnet wire

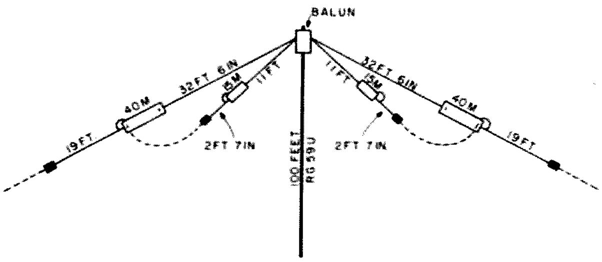

Fig. 1.

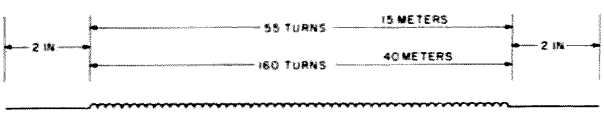

Fig. 2. Don't forget to leave 2" on each end of each coil.

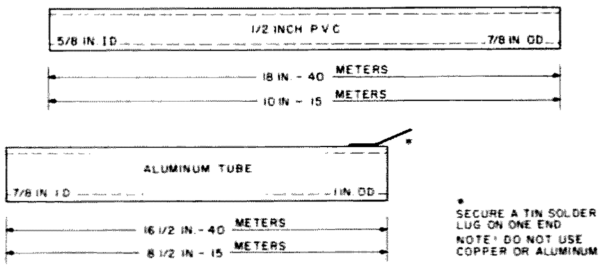

Fig. 3.

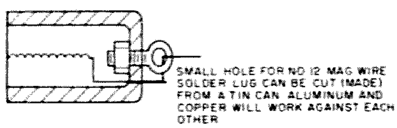

Fig. 4. The coil will expand to make a nice fit inside the PVC tube. The aluminum fits snugly over the PVC, and the cap rims help hold the aluminum tube in place. It all makes a very nice looking assembly.

Josef Bernard K2HUF

New York NY 10011

Liberate Your Wilson HT

-- who needs nicads?

I am sure that many hams will agree with me that the Wilson HTs are among the best buys on the market. Their performance/price ratio is significantly greater than that of many other units intended for the same purpose. There are, however, several features which those other units offer which the Wilson could benefit by, and one of the most valuable is the ability to operate from a power supply other than the self-contained nicads.

As a ham with a large investment in low band equipment and getting deeply involved in slow scan (more money), I cannot afford both a base and a portable/mobile 2 meter rig and must make my Wilson perform both functions. Since I'm a rag chewer by nature and the Wilson's nicads are useful only until their charge gives out, the ability to operate my HT from an external dc power supply became a necessity if I were to be able to remain on the air for any extended period of time.

While it is possible to access the battery pack through the fitting at the top of the rig (only when the unit is turned on), this is both physically inconvenient and electrically unsound. There had to be another way.

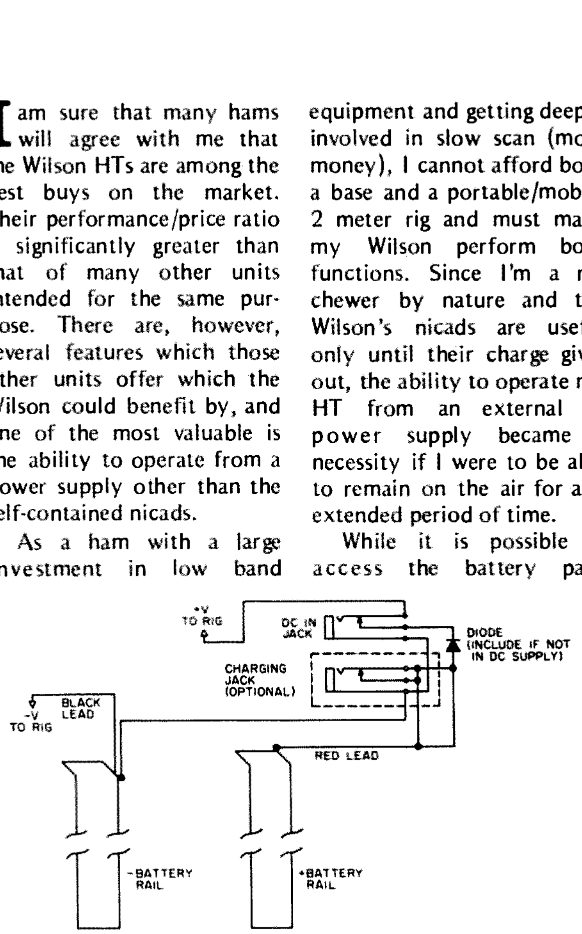

Fig. 1. Rear view of front half of Wilson case (not to scale).

One solution to my predicament was proposed by a friend who owns two battery trays for his own Wilson. He has taken the second tray (*sans* batteries), drilled a small hole in its base, and connected wires to the internal rails which normally carry power from the batteries to the electronics. Outside his Wilson, these wires are attached to a suitable dc supply, and he is in business.

With all due respect, I find several drawbacks to this system. First, when you want to switch from the nicads to external power, it is necessary to remove the one battery tray and insert the other. This can be somewhat inconvenient if you are in a big hurry or want to travel light.

Second, with those wires coming out of the bottom of the rig, its equilibrium becomes rather unstable and, while I know from experience that the Wilson is capable of sustaining a fall of reasonable distance, I prefer to verify this knowledge as infrequently as possible. The only safe way of using this arrangement is with the rig lying on its back — somehow inelegant as well as inconvenient. Consequently, I tried a different approach.

I went about adding external dc capability to my Wilson by installing a jack in the side of the transceiver. The wiring is such that, normally, the rig functions as usual from the internal nicads. When the plug from the power supply is inserted, however, the batteries are disconnected from the rest of the rig, and dc from the outside world flows directly into the Wilson. An obvious advantage of this setup is that you never have to fuss with, or even consider, a second battery tray. A less obvious advantage is that while you are running the HT from outside power, you can be charging its batteries at the same time. More about the use of a second jack for charging purposes later.

Installation of the jack(s) is easy — all you really require is the nerve to puncture the hide of the HT. By no means should the hole be made with a drill — one slip or ill-timed sneeze could wreak havoc with the rig and your wallet! Instead, start the hole with a pencil tip soldering iron and go only far enough to just begin to penetrate the inside wall of the case. The hole may then be enlarged with a tapered reamer until it is the right size to snugly accommodate the jack. It may take several days to work up the courage to do this, but it's worth working up to and once you've done it, you'll find it hard to resist doing it again.

The jack I used is an enclosed miniature 1/8" normally-closed phone type

(Radio Shack 274-296). Properly located, two of these will fit comfortably within the Wilson. The obvious — and probably only — place to install the jack is on the right-hand side of the unit (as seen from the front) in the front half just above the battery pack.

There is plenty of room if you pay attention to one or two details. Allowance should be made to clear the channel selector switch which will be just above the jack, and to clear the metal brace which, it would appear, serves to keep you from crushing the HT in your grip if you squeeze the PTT lever too enthusiastically. Careful planning will enable you to pinpoint the correct spot.

In working on my rig, I tread a little too cautiously and placed the dc jack a bit on the low side, probably because I was trying to avoid conflict with the trimpot for my touchtone pad. Even so, I still have room for the addition of a charging jack, so, being forewarned, you should have no difficulties at all.

The unswitched terminal of the dc jack (see Fig. 1) is connected to the ground rail (black wire) of the battery tray slide. The hot lead (red, from the other rail) is broken and connected across the other two terminals of the jack. The battery side of this red lead should be connected to the switched terminal. This way the internal current flow will be normal when no plug is inserted, but insertion of the dc plug will break the battery line and allow current from the external supply through the rig's electronic innards.

Similarly, a second jack, for battery charging from the outside, may be installed ahead of the first and wired the same way. Normally, the HT will operate as usual, but with a plug inserted in the charger jack, the batteries will be placed in parallel with the charger. While it is not recommended that the Wilson be operated from its, or any other, battery charger, with this arrangement is is possible to charge the batteries while operating from the external dc supply at the same time.

Incidentally, the power supply which I use was adapted from the one detailed by WA8WVF in the September, 1976, issue of *73*. My supply uses smaller power tab type transistors, available from Radio Shack (276-636), which seem to function very comfortably at the level required by the Wilson.

An out-of-tolerance 15 V zener together with a diode in the line (for both slight voltage dropping and *reverse polarity protection;* install such a diode at the jack if your power supply doesn't incorporate one, to save your nicads unnecessary grief) feed my Wilson about half a volt more than it normally gets from its battery pack, and the rig has been operating very happily and successfully in this fashion for a number of months.

My thanks to W2YHX and WA2UAQ for their inspiration and urging on to better things, and best of luck to you in making this simple, but extremely worthwhile, modification. ■

Novice Antenna Specials

-- tips for that first antenna

William E. Hood W2FEZ
116 W. Park St.
Albion NY 14411

When a Novice receives his first license and is ready to get on the air, there comes the final portion of the volunteer examiner's responsibility which many either fail to realize or completely forget. Here is a newly-licensed individual whose knowledge of amateur radio is largely theoretical – one for whom the minor technicalities of getting on the air can present a major stumbling block unless that individual who got him into this in the first place is still with him, ready to help him over the few pitfalls in the process of getting started.

To the newly-licensed Novice, especially if he is a young person, the task of erecting his first antenna can be a formidable one. Then, if he makes one small mistake here or there, mistakes that the books don't always warn him against, he may be in for disappointment and discouragement. This article, then, is written with the beginner in mind, in hopes that it might help him to do the job right and start him out with an antenna that will properly introduce him to a truly rewarding hobby.

It's not nice to fool Mother Nature. She has her rules which, if obeyed, will serve you well and, if ignored, will trip you up. An antenna is a piece of equipment all in itself. It must change the alternating currents generated by your transmitter into radio waves; it must change radio waves into alternating currents from which the receiver can then recover the intelligence. So long as the rules are met, you can make your antenna any way you like.

In part, the rules are: The antenna must run in a straight, or nearly straight, line. It *must* be resonant. It should be suspended as high above the ground as possible, and as clear as possible of substantially large, grounded objects. While there are many antennas that are exceptions to these rules, they apply to any kinds of antennas that are relatively easy to install and tune.

What Kind of Antenna Do You Want?

The vast majority of antennas used by amateurs transmitting on Novice frequencies are distributed through two classes: dipoles and endfed wires.

The Dipole

A dipole is made of two pieces of wire, strung end-to-end, with the coax feedline connected in the center. The overall length of the combined two pieces of wire must be one half wavelength. The exact size may vary with the kind of wire you use, the height of the antenna above the ground, the conductivity of the ground in your location, and a few other things. Here are some sizes that will get you into the right ball park. (Note: these values are aimed at the centers of the Novice bands.)

80 meters	**125' 7"**
40 meters	**65' 5½"**
15 meters	**22' 1½"**
10 meters	**16' 7½"**

It is best if the antenna is run in a straight line, although some small amount of angle between the two halves can be tolerated. If you run the two halves side-by-side, as

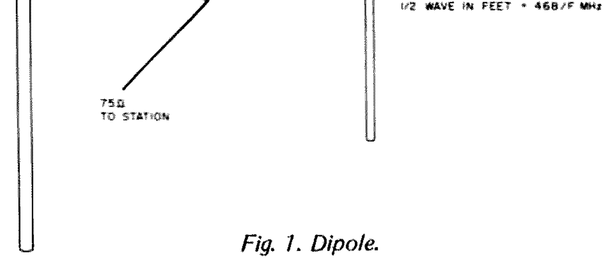

Fig. 1. Dipole.

one Novice almost did, it simply won't work! Support your wires with any strong insulating cord from trees, poles, buildings, or whatever happens to be handy. Fasten the cords to the antenna with glass, plastic, or ceramic insulators. In the center, use another insulator similar to those used at the ends.

Feed a dipole with 75 Ohm coaxial line. Type RG-59/U is adequate. You can use RG-11/U also, but it's bulky and expensive. Wrap the coax around the center insulator, tape it in place, and connect the conductors, one to each antenna wire.

The Inverted Vee

The inverted vee is a variation of the dipole that has provided excellent results for a great many hams. Unlike the dipole, the inverted vee is supported in the center, with the ends staked in place close to the ground. At this point, I will caution you to have the ends of the wires high enough that your neighborhood kid can't reach them. Otherwise, he'll be sure to grab them when you're transmitting, to the tune of a couple of thousand volts.

The angle between the two halves of an inverted vee should be between 90° and 120° for best results. The vee form factor changes the length needed to resonate your antenna. Here are the total lengths required for the Novice bands:

80 meters	124' 7"
40 meters	64' 11"
15 meters	21' 11"
10 meters	16' 6"

The inverted vee should be fed with 50 Ohm coax. Use type RG-58/U. RG-8/U can also be used, but it is more bulky and expensive.

The Endfed Wire

The endfed wire is the simplest of the antennas to erect, and can be the answer if your shack is on an upper floor. However, it requires a tuner, and can be a stinker to tune up for the first time. Also, if it isn't tuned up right, it can produce stray rf voltages floating around your shack and showing up where least welcome.

The length of an endfed wire is the most tolerant of mistakes (among the three antennas discussed here). In fact, an experienced amateur can load up almost any random length of wire. Since it is brought directly to your shack, there is no feedline as such. The tuner can be connected to the antenna with either 50 or 75 Ohm coax, but not both.

For a tuner, you can use the "Lunch Box" tuner described in the November/December, 1975, issue of *73*.

Bring the coax from your antenna, or tuner, through a coaxial lightning arrester, a low pass filter (if you use one), and a reflected power meter to the antenna relay or transceiver. Bring a wire from the lightning arrester, and a wire from each piece of equipment, to a common terminal in your shack, which will be your prime ground terminal. Don't depend on the shield in the coax for this connection. Run a heavy conductor from your prime ground terminal to your final earth-ground connection (a water pipe, driven rod, or several square feet of buried screen). A good ground is essential for the best operation of your station.

How to Tune Your Antenna

Generally, most antennas will work OK if cut from the basic antenna formulas, or if cut carefully to the sizes given in the preceding paragraphs. Once in a while you will find one needs further matching. We call the process "pruning." If the reflected power meter indicates a standing wave ratio of 2 or higher, you should prune the antenna. If the swr is 1.5 or less, leave it alone. Between 1.5 and 2, it's your decision.

It's a good idea to secure the help of an experienced amateur if you prune your antenna. With a little care and

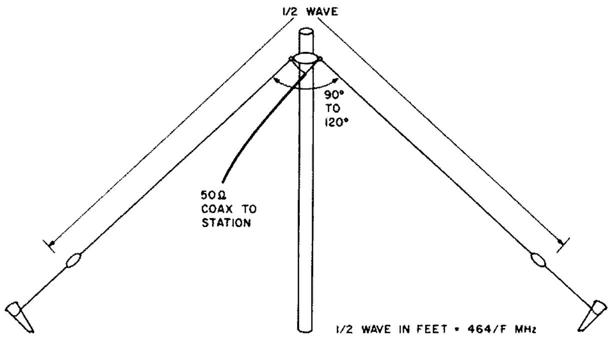

Fig. 2. Inverted vee.

common sense, however, you can do it yourself, and there's no time like the present to learn. You will need a grid dip meter. This can be borrowed from a local ham, if you can locate one, or it can often be located through a ham club. You will also need a receiver with a fairly accurate dial. *Never* depend on the dial calibrations of a grid dip meter unless it comes from a commercial lab. Even then be ready to question it.

The swr of the antenna can give you some idea which way you will have to go. If it is lowest at the high end of the band, the antenna is too short; if it is lowest at the low end of the band, the antenna is too long. To find out exactly how much to change the length, you must find out just where the antenna is resonant. That's where the grid dipper comes in.

Let's first consider the process of pruning a dipole. Support the dipole, stretched out in a straight line, at a height where you can easily reach it. Remove the coax and short the two halves together. Hold the grid dip meter with the coil just touching, but not making electrical contact with, the center of the antenna wire. Very slowly tune the grid dip meter through the suspected resonant frequency of the antenna. You will notice a pronounced dip in the meter reading. The bottom of this dip is at the resonant frequency of the antenna. Slowly move the coil away from the antenna, tuning back and forth over the resonant frequency until the dip is barely noticeable. When the meter reads at the lowest point, it is tuned to the antenna's resonant frequency. Now tune your receiver until you zero-beat the meter's oscillation, and read the frequency from the receiver's dial.

If you are checking an inverted vee, leave it in place and connect a turn or two of wire across the end of the coax. Couple the coil of the grid dip meter into this link, and spot the resonant frequency as in the preceding paragraph.

Once you have the resonant frequency spotted, you're almost there. Now you must adjust the antenna length to make it resonant where you want it. If the resonant frequency is too high, the antenna must be lengthened; if it is too low, the antenna must be shortened. Just how much depends on how far off the antenna's frequency is from where you want it. Find the *difference* between the antenna's resonant frequency and the center frequency of the band you are using. Multiply that difference by the factor given below:

80 meters	0.4
40 meters	0.11
15 meters	0.01
10 meters	0.007

The result is the amount, in inches, that must be taken from or added to your antenna. Remove or add exactly half this amount to each half of the antenna, and recheck swr. If you did it right, you

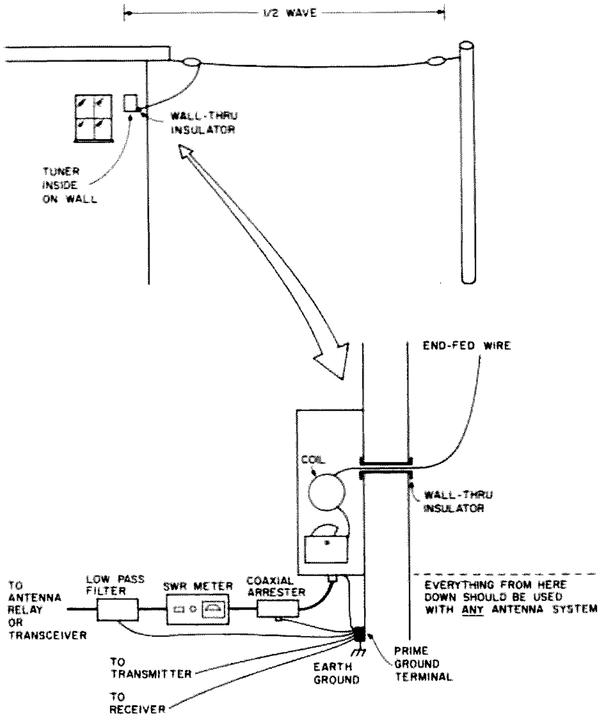

Fig. 3. Endfed wire.

will find a tremendous improvement.

Example: Charlie Brown finds his antenna is actually resonant at 6575 kHz. He wants it resonant at 7125 kHz. 7125 - 6575 = 550. 550 x 0.11 = 60.5. Charlie cuts 30¼ inches from each half of his antenna, and it will resonate at 7125. The discrepancy has been exaggerated to better illustrate the principle.

Example: Linus finds his antenna is resonant at 3875 kHz, and he wants it at 3725. 3875 - 3725 = 150. 150 x 0.4 = 60. He adds 30 inches to each half of his antenna, and it's resonant at 3725. Again, the amount of difference shown is more than you're likely to come up against.

Tuning An Endfed Antenna

There isn't much need to adjust the length of an endfed antenna, since the tuner makes up for that. If you've never done it before, you may want to tune your transmitter into a dummy load first. This isn't absolutely necessary, however. A grid dip meter can help, but you can get by without it. If you don't have something to read swr, get it.

With a grid dip meter:

Connect the antenna to the tuner, disconnect the transmitter, and short the coax connector. Set the grid dip meter to the center of the band you are using, spotting the frequency on your receiver. Couple the grid dip meter into the tuner and adjust the capacitor until you get an indication on the meter. If the meter seems to be approaching an indication with the tuner capacitor fully meshed, add a turn to the tuner coil. If the meter seems to be approaching an indication with the tuner capacitor all the way out, remove a turn from the tuner coil.

Without a grid dip meter, or after finding resonance with a grid dip meter:

Reduce the drive level in your transmitter as far as you can and still get rf out. (At this point it helps if the transmitter has already been tuned into a 50 Ohm dummy load.) Set the swr meter for reflected power. Tune the capacitor in the tuner for a dip in swr. If it seems to be approaching a dip with the capacitor all the way in, turn off the transmitter and add a turn to the tuner coil. If it seems to be approaching a dip with the capacitor all the way out, turn off the transmitter and remove a turn from the tuner coil. *Never* touch the coil while the transmitter is operating, unless you get the jollies by being tickled with a few thousand volts of rf.

Once the tuner is resonated, increase the drive in your transmitter and retune for a dip in swr. You may notice that you don't necessarily get the maximum forward drive at the same point where you get minimum swr. Redip the plate tuning of the transmitter, and you're ready to go. With subsequent changes in frequency, simply touch the tuner capacitor for minimum swr. It takes a bit of practice to get used to handling endfed antennas, but those who have mastered the art swear by them.

Having resonated an antenna, the next step is multiband operation. With dipoles or inverted vees, there's nothing at all wrong with connecting several antennas to one piece of coax. They do become trickier to tune, however.

Trap antennas simply utilize the frequency selection characteristics of parallel wavetraps to provide an end of the antenna for one frequency while letting others go on to the ends of the wire. These can be resonated in the same manner as dipoles or inverted vees, remembering that the higher frequency portion, in the middle, must be resonated first, then the lower portion at the ends.

The techniques outlined here have been very basic — old hat to most amateurs, but I hope the Novice reader may find this article useful in getting over that all-important hurdle and getting on the air.

Good luck, and welcome to ham radio! ■

Sound Operated Relay

-- for the ultimate security system

Ralph Taggart WB8DQT
602 So. Jefferson St.
Mason MI 48854

There are numerous occasions when it would be nice to have a relay circuit that could be conveniently triggered by sound. Applications include automatic recording of the output of a monitor receiver that is not equipped with a COR circuit, automatic recording of data from any audio link, design of VOX circuits for RM or home brew sideband equipment — in short, lots of possibilities. In most of these applications, it would also be nice to have an adjustable time delay so that once triggered, the control circuit would remain actuated for a set period in the absence of further input, thus saving wear and tear on the recorder when monitoring a channel where rapid callbacks could be expected, where data dropouts might occur, or in a VOX circuit where we would want to avoid cycling the relay during momentary speech pauses. A great many of the circuits that can accomplish the relay/time delay function have several drawbacks, including undue circuit complexity or unwanted variation in the time delay. While looking through application notes for the versatile Signetics NE-555 timer IC[1], I realized that this chip could be very effectively put to use in a VOX circuit, something which is probably done every day in industry, but an application which is little used in amateur designs.

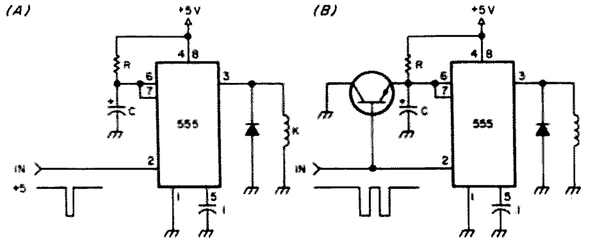

Fig. 1. Basic timer circuits for the NE-555. (a) Shows the basic timer. A momentary LOW at pin 2 causes the 5 volt reed relay (K) to pull in for a time period equal to 1.1RC. This circuit cannot be triggered again until the timing cycle is completed. (b) Shows the addition of a PNP transistor that permits the circuit to be continuously triggered during a timing cycle. As long as the input lows continue to arrive within the timing period (again 1.1RC), the relay will remain in the pulled-in condition. The relay will only drop out if a period of 1.1RC elapses between pulses.

A basic NE-555 timer circuit is shown in Fig. 1. If the input is momentarily pulled low, the timer will pull in the reed relay for a period determined by R and C in the timer circuit. The relay pull-in time can be computed from the formula $t = 1.1$ RC. If we use a 100k resistor for R and a 47 mF capacitor for C, the relay would pull in for $1.1\ (1\text{x}10^5)\ (4.7\text{x}10^{-5})$ or approximately 5.2 seconds. By itself, this circuit is not ideal for VOX, for it is not possible to retrigger the circuit until the timing cycle has been completed. By adding a simple PNP transistor, as shown in Fig. 1(b), it is possible to retrigger it. This circuit is widely used as a missing pulse detector, for the output will remain high (relay pulled in) as long as trigger pulses continue to arrive. Used as a missing pulse detector, one would normally set the timer for a period slightly longer than the expected interval between pulses. As long as the pulses arrive on schedule, the timer is repetitively triggered, but it will drop out as soon as a pulse is missing from the input train. This circuit configuration can easily be used in a VOX mode, for if we can pull the input low with peaks in an audio waveform, the relay will close and remain closed as long as there is audio input. When the input audio ceases, the relay will drop out after a time period determined by the RC formula noted earlier.

All that is required to convert the missing pulse detector to an audio triggered circuit is the addition of a single transistor as noted in Fig. 2. If this transistor conducts, it will trigger the timer. By adjusting the 10k input pot to just short of the point where the timer is triggered — in other words, biasing the transistor to just short of the point where it is ready to take off — a very small audio voltage on the input will trigger the timer and keep the relay in as long as the audio signal is present. The circuit is more than sensitive enough to respond to a signal tapped off the speaker leads of a monitor receiver, keyer, intercom, or what have you. Obviously, if you want to use the relay with a monitor receiver, the receiver should be equipped with a squelch circuit, other-

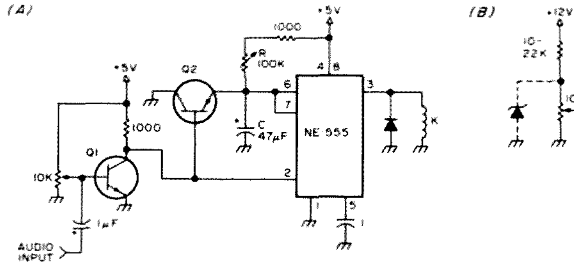

Fig. 2. (a) The basic audio operated relay. Q1 is any general purpose NPN transistor, while Q2 is an equally non-critical PNP unit. The 10k input pot is adjusted (starting with 0 V on the base of Q1) to a point just short of where Q1 turns "ON" as indicated by K pulling in. The closer the bias is set to this point, the less audio voltage at the input required to trigger the circuit. K is any 5 V reed relay. With the values shown for R (100k pot) and C (47 mF/20 V tantalum capacitor), timing values from .05 to slightly over 5 seconds can be achieved. In practice, timing below approximately 0.25-0.5 seconds is impractical as the relay will cycle between syllables. Values in excess of 5 seconds can be obtained simply by increasing the values of R and C. (b) Shows the addition of a 22k series resistor to the 10k input pot if a 12 V supply is used. If voltage fluctuations are expected on the supply line, a 4-6 V 1 W zener can be added as shown. Adjust the value of the series resistor in this case to provide the proper regulated voltage at the top of the input pot with the expected supply variations. The timer will function quite well at 12 V if a suitable 12 V reed relay is used at K. The diode across the relay coil simply provides surge protection from the back EMF developed across the relay coil and any general purpose 1 A diode rated at 50 or more volts may be used.

wise the background noise will trigger the relay just as effectively as the voice signals or data we wish to record. The attack time of the circuit is limited only by the pull-in time of the relay, which is very short in the case of typical reed relays. The timer will operate quite nicely at 12 volts, but in this case it is wise to include a series resistor at the top of the input pot shown in Fig. 2(b) to keep the base voltage to Q1 at a safe level. The timer will retain its accuracy with very wide swings in supply voltage, but since the bias level is critical for Q, it would be wise to include a 4-6 V zener on the input pot to stabilize the bias voltage in a mobile installation or situations where an unregulated supply voltage is used. The chip will handle virtually any reed relays at 5 or 12 volts, but if you should require a larger relay in your application, you should consider using the reed relay to trigger the larger unit or interfacing a transistor at the timer output to pull in a conventional open frame or plug-in relay.

The handful of parts used in the circuit are easily assembled on a small piece of perfboard and component placing is non-critical. This circuit has been used in a variety of applications in my own shack, including making tapes from the weather satellite receiver, logging calls on local "experimenter" simplex channels, automatically recording weather alerts, and in a variety of system control applications. It works like a charm despite the minimal component investment! ■

Traffic Handling Explained

-- a lost art?

Ralph A. Giffone WB2YKG
963 East 105th Street
Brooklyn NY 11236

I am sure that many of you have heard the terms ARPSC, AREC, and NTS. I am sure that you were as equally confused with those terms as you were with these: public service, traffic handling, emergency communications.

"What are they talking about?" you have probably asked yourself more than once, but probably gave up trying to understand soon after.

I am going to explain those terms and the ideas behind them, with the hope that it will cause you to take an interest and pursue that interest.

The National Traffic System (NTS) and the Amateur Radio Emergency Corps (AREC) are actually the Amateur Radio Public Service Corps (ARPSC) divided into two parts: an emergency division (AREC) and a traffic division (NTS). The AREC is usually dormant during normal times (no emergency), whereas NTS is always active. This does not mean, however, that the AREC is not ready. It's standing by, to be activated in an emergency.

Since my main objective is to get you into traffic handling, I will try to give you as complete a background of NTS that is possible without getting too technical.

The NTS is a major network composed of many smaller, interdependent networks (nets, for short). These smaller nets are categorized (from biggest to smallest) as local nets, section nets, region nets, and area nets.

The purpose of NTS is to handle third party traffic during normal times and, ultimately, to pass emergency traffic during emergencies. By passing traffic, we not only perform a public service, but we also train for the times when there can't be any mistakes, those life and death situations that we call emergencies.

You say you don't know what third party traffic is? You may think of third party traffic as any communication (phone patches, radiograms, etc.) transmitted via amateur radio for a third party (someone other than yourself). The bulk of the traffic handled on NTS are "radiograms." These radiograms (written messages in a standard form) may be relayed to their destination by way of the National Traffic System.

Let's see how NTS "gets you there" (your message, I mean).

Let's assume that you are living in New York City. Your neighbor wants to send birthday greetings to her Aunt Enna in Los Angeles, California. Here's how your message gets to California: First, you must put the message in the ARRL's standard amateur message form (a minor and simple technicality). Next thing you would do is check into your section net, which is, in this case, the New York City-Long Island Section Net (NLI). A section net is composed of people from their respective ARRL section (NLI in this case). If you have any traffic whose destination is within the section, it can be passed directly on your section net.

Since your message is for California, and not within the NLI section, it must be taken to another net – a region net. A region net is composed of representatives from each of the respective section nets of that region. (By the way, this representative is called a liaison, and is the person who brings all the outgoing traffic of one net to another net.)

Since the NLI section is part of the second region, all the traffic coming from this net must go to the second region net (2RN). The liaison appointed for that night will take your message from you, and then check into 2RN with that same message.

There are four liaisons who check into the second region net, one from the New York State Section Net (NYS), one from the New Jersey Section Net (NJN), one from NLI (the one that you check into), and a station that will go to the Eastern Area Net. Now . . . if there is any traffic for any of the sections in the second region, it can be passed directly on this net. For example: The NYS liaison has one message for New Jersey. The liaison from NJN will take this message. He will take it back with him to his section net, when he checks in later, to be delivered to the proper town.

If there is any traffic whose destination is not within the region, it must be taken to yet another net, the Eastern Area Net (EAN). Such is the case with your message. Your message is for

California, and that is certainly not part of the second region. There will be a liaison at the second region net who will take your traffic to the Eastern Area Net.

If you can see the pattern now, you will note that California is not part of the EAN either, but must be sent to the Pacific Area Net (PAN).

When the liaison with your traffic checks into EAN, he will relay the message to an operator in the TransContinental Corps (TCC). TCC is the organization that relays messages to and fro between PAN, CAN, and EAN – Pacific, Central, and Eastern Area Nets respectively. The message will then be sent by way of TCC to the PAN. Your message then undergoes the previous processes in the reverse order: From PAN (an area net), to the sixth region net (a region net), to the appropriate California section net.

The people who check into this section net are people from all over the section. A station in Los Angeles will check in and take your traffic. This station would then deliver your message to your neighbor's Aunt Enna by telephone and/or mail. He will usually take the time to explain how the message got there, so as not to baffle its recipient.

That is how your traffic gets from place to place within the National Traffic System. Would you believe that this usually takes place within about three hours?

There are three major purposes (in my eye) of NTS and traffic handling: public service, emergency communications, and fun.

Most non-hams have a dim view of amateur radio because their only experience with radio has been that of TVI and RFI. Handling their traffic shows them that ham radio has a purpose, and can be useful to them. I used to have a problem with my neighbor, but once I started handling her traffic, she never mentioned anything again!

Knowing how nets operate and how you yourself must act on a net increases NTS's effectiveness during emergencies. We are not usually so lucky: Many inexperienced people check into nets (wanting to help, of course), but usually decrease the net's efficiency because of this inexperience. A well-trained amateur is NTS's biggest asset.

Traffic handling is fun. I cannot actually pinpoint the reason, but once I started, I was hooked.

By this time, I am sure that many of you would like to know more.

The first net that you can actually check into is the section net; it is unwise to check into a higher net if you lack the proper experience. The section net is, as I said before, composed of people from your respective ARRL section. Most section nets have a roster of about 30 people, but this usually depends on what the ham population is in that area. You realize, of course, that it is a rare occasion when more than half the net's membership checks in on any given night (this is especially true on CW nets). A section net with a roster of thirty will usually average six to twelve check-ins per night.

ARRL Operating Form #9 gives you the standard amateur message format. On the opposite side are Q signals and abbreviations for traffic net use.

AMATEUR MESSAGE FORM

Every message originated and handled should contain the following component parts in the order given.

I PREAMBLE
- *a.* Number (begin with 1 each month or year)
- *b.* Precedence (R, Q, P or EMERGENCY)
- *c.* Handling instructions (optional, see text)
- *d.* Station of Origin (first amateur handler)
- *e.* Check (number of words/groups in text only)
- *f.* Place of Origin (not necessarily location of station of origin)
- *g.* Time Filed (optional with originating station)
- *h.* Date (must agree with date of time filed)

II ADDRESS (as complete as possible, include zip code and telephone number)

III TEXT (limit to 25 words or less, if possible)

IV SIGNATURE

CW MESSAGE EXAMPLE

I NR 1 R HXA W1AW 8 NEWINGTON CONN 1930Z July 1
a b c d e f g h

II DONALD R SMITH $\overline{AA}$
164 EAST SIXTH AVE $\overline{AA}$
NORTH RIVER CITY MO 00789 $\overline{AA}$
FONE 733 3967 $\overline{BT}$

III HAPPY BIRTHDAY X SEE YOU SOON X LOVE $\overline{BT}$

IV DIANA $\overline{AR}$

CW. Note that X, when used in the text as punctuation, counts as a word. The prosign $\overline{AA}$ separates the parts of the address, $\overline{BT}$ separates the address from the text and the text from the signature. $\overline{AR}$ marks end of message; this is followed by B if there is another message to follow, by N if this is the only or last message. It is customary to copy the preamble, parts of the address, text and signature on separate lines.

RTTY: Same as cw procedure above, except (1) use extra space between parts of address, instead of $\overline{AA}$; (2) omit cw procedure sign $\overline{BT}$ to separate text from address and signature, using line spaces instead; (3) add a CFM line under the signature, consisting of all names, numerals and unusual words in the message in the order transmitted.

PHONE: In general, use *prowords* in place of procedural signals or *prosigns*. The above message on phone would go something like this: "*Message Follows* Number one, routine, HX Alpha, W1AW, *check* eight, Newington, Connecticut, one eight thuhree zero zulu, July one, *to* Donald *Initial* R Smith, *Figures* one six fower, East Sixth Avenue, North River City, Missouri zero zero seven eight nine, Fone sev-ven thuhree thuhree, thuhree niyen six eight. *Break* Happy Birthday X-ray see you soon X-ray love *Break* Diana, *End of Message, Over*." Speak in measured tones, emphasizing every syllable. Spell out phonetically all difficult or unusual words, but do *not* spell out common ones.

PRECEDENCES

The precedence will follow the message number. For example, on cw 207R or 207 EMERGENCY. On phone, "Two Zero Seven, Routine (or Emergency)."

EMERGENCY – Any message having life and death urgency to any person or group of persons, which is transmitted by amateur radio in the absence of regular commercial facilities. This includes official messages of welfare agencies during emergencies requesting supplies, materials or instructions vital to relief of stricken populace in emergency areas. During normal times, it will be *very rare*. On cw, this designation will *always* be spelled out. When in doubt, do *not* use it.

PRIORITY – Important messages having a specific time limit. Official messages not covered in the "Emergency" category. Press dispatches and other emergency-related traffic not of the utmost urgency. Notification of death or injury in a disaster area, personal or official. Use the abbreviation P on cw.

INQUIRY – Messages pertaining to the health or welfare of persons in a disaster should carry this precedence, which is abbreviated to Q on cw. These messages are handled *after* PRIORITY traffic but before ROUTINE.

ROUTINE – Most traffic in normal times will bear this designation. In disaster situations, traffic labeled "Routine" (R on cw) should be handled *last*, or not at all when circuits are busy with emergency, priority or inquiry traffic. Most traffic handled on amateur circuits in normal times will fall in this category.

Handling Instructions

HXA – (Followed by number.) Collect landline delivery authorized by addressee within .... miles. (If no number, authorization is unlimited.)
HXB – (Followed by number.) Cancel message if not delivered within .... hours of filing time; service originating station.)
HXC – Report date and time of delivery (TOD) to originating station.
HXD – Report to originating station the identity of station from which received, plus date and time. Report identity of station to which relayed, plus date and time, or if delivered report date, time and method of delivery.
HXE – Delivering station get reply from addressee, originate message back.
HXF – (Followed by number.) Hold delivery until .... (date).
HXG – Delivery by mail or landline toll call not required. If toll or other expense involved, cancel message and service originating station.

This prosign (when used) will be inserted in the message preamble before the station of origin, thus: NR 207 R HXA50 W1AW 12 .... (etc.). If more than one HX prosign is used, they can be combined if no numbers are to be inserted, otherwise the HX should be repeated, thus: NR 207 R HXAC W1AW .... (etc.), but: NR 207 R HXA50 HXC W1AW .... (etc.). On phone, use phonetics for the letter or letters following the HX, to insure accuracy.

OPAID 9 81075 — ARRL, 225 Main St., Newington, CT 06111

ARRL QN SIGNALS FOR CW NET USE

QNA*	Answer in prearranged order.
QNB*	Act as relay Between.....and.....
QNC	All net stations Copy. I have a message for all net stations.
QND*	Net is Directed (controlled by net control station).
QNE*	Entire net stand by.
QNF	Net is Free (not controlled).
QNG	Take over as net control station.
QNH	Your net frequency is High.
QNI	Net stations report In.* I am reporting into the net. (Follow with a list of traffic or QRU.)
QNJ	Can you copy me? Can you copy.....?
QNK*	Transmit messages for.....to.....
QNL	Your net frequency is Low.
QNM*	You are QRMing the net. Stand by.
QNN	Net control station is..... What station has net control?
QNO	Station is leaving the net.
QNP	Unable to copy you. Unable to copy.....
QNQ*	Move frequency to.....and wait for.....to finish handling traffic. Then send him traffic for.....
QNR*	Answer.....and Receive traffic.
QNS	Following Stations are in the net.* (Follow with list.) Request list of stations in the net.
QNT	I request permission to leave the net for.....minutes.
QNU*	The net has traffic for you. Stand by.
QNV*	Establish contact with.....on this frequency. If successful, move to.....and send him traffic for.....
QNW	How do I route messages for.....?
QNX	You are excused from the net.* Request to be excused from the net.
QNY*	Shift to another frequency (or to.....kHz) to clear traffic with.....
QNZ	Zero beat your signal with mine.

*For use only by the Net Control Station.

Notes on Use of QN Signals

The QN signals listed above are special ARRL signals for use in amateur cw nets *only*. They are not for use in casual amateur conversation. Other meanings that may be used in other services do not apply. Do not use QN signals on phone nets. *Say it with words.* QN signals need not be followed by a question mark, even though the meaning may be interrogatory.

INTERNATIONAL Q SIGNALS

A Q signal followed by a ? asks a question. A Q signal without the ? answers the question affirmatively, unless otherwise indicated. See the ARRL *Handbook* and *Operating an Amateur Radio Station* for an expanded list.

QRA	What is the name of your station?
QRG	What's my exact frequency?
QRH	Does my frequency vary?
QRI	How is my tone? (1-3)
QRK	What is my signal intelligibility? (1-5)
QRL	Are you busy?
QRM	Is my transmission being interfered with?
QRN	Are you troubled by static?
QRO	Shall I increase transmitter power?
QRP	Shall I decrease transmitter power?
QRQ	Shall I send faster?
QRS	Shall I send slower?
QRT	Shall I stop sending?
QRU	Have you anything for me? (Answer in negative.)
QRV	Are you ready?
QRW	Shall I tell.....you're calling him?
QRX	When will you call again?
QRZ	Who is calling me?
QSA	What is my signal strength? (1-5)
QSB	Are my signals fading?
QSD	Are my signals mutilated?
QSG	Shall I send.....messages at a time?
QSK	Can you work breakin?
QSL	Can you acknowledge receipt?
QSM	Shall I repeat the last message sent?
QSO	Can you communicate with.....direct?
QSP	Will you relay to.....?
QSV	Shall I send a series of V's?
QSW	Will you transmit on.....?
QSX	Will you listen for.....on.....?
QSY	Shall I change frequency?
QSZ	Shall I send each word/group more than once? (Answer, send twice or.....)
QTA	Shall I cancel number.....?
QTB	Do you agree with my word count? (Answer negative.)
QTC	How many messages have you to send?
QTH	What is your location?
QTR	What is your time?
QTV	Shall I stand guard for you.....?
QTX	Will you keep your station open for further communication with me?
QUA	Have you news of.....?

ABBREVIATIONS, PROSIGNS, PROWORDS

CW	PHONE (meaning or purpose, exception obvious)
$\overline{AA}$	(Separation between parts of address or signature.)
AA	All after (used to get fills).
AB	All before (used to get fills).
ADEE	Addressee (name of person to whom message addressed).
ADR	Address (second part of message).
$\overline{AR}$	End of message (end of record copy).
ARL	(Used with "check," indicates use of ARRL numbered message in text.)
$\overline{AS}$	Stand by; wait.
B	More (another message to follow).
BK	Break; break me; break-in. (interrupt transmission on cw. Quick check on phone.)

A radiogram message blank. Although not necessary for handling traffic, they do give your messages a "spiffy" look.

If you are in the dark as to what net meets in your area, you might send for the ARRL Net Directory (an SASE will bring a quick response). This lists all NTS nets, as well as other nets which do not have traffic handling as their main purpose. The net directory will help you find any NTS net. They are listed by state and frequency as well as by the net's name.

Most section CW nets meet anywhere from 6 pm and later (usually) and are almost exclusively on 80 meters. The phone nets, however, are of different case. They usually meet during the day or in the late afternoon. The area phone nets usually meet on 40 meters (for obvious reasons).

There are generally three types of traffic nets: CW nets, phone nets, RTTY nets. All are quite useful, but for different purposes. RTTY comes in handy when you have to handle bulk traffic, that is, many messages all at once. Tape operation gives this advantage. Unfortunately, there are very, very few RTTY nets in NTS. Phone nets, as well as RTTY nets, are mainly for those who are experienced in traffic handling. CW nets are of two kinds: high speed and slow speed. The high speed net usually operates at a speed of approximately 18 wpm and is usually composed of experienced traffic handlers.

A very valuable net to those beginning in traffic handling is the slow speed net. The slow speed net serves many purposes. One of its greatest purposes is to train inexperienced rookies and turn them into veteran traffic handlers. This net is for making mistakes and no one will look down on you for making them. (Don't get me wrong. I am not saying that high speed nets are for the experienced and that slow speed nets are for the inexperienced only. This would be terrible. The inexperienced must learn through the help and examples set by the experienced. Believe me, everyone is usually willing to help.)

The slow speed net used to mainly train Novices, Generals, etc., but now with the new regulations, even Technicians can check into slow speed nets. Take my word, traffic handling will increase your code speed by plenty, and if you're a Tech or Novice who wants to upgrade, it will help a lot!

In time, if you become deeply involved in traffic handling, you may find your name printed in *QST* on the Public Service Honor Roll and Brass Pounder's League. But don't think that your name has to be there to be important. The fact is that every single person is important whether he passes thousands of messages or just one. Remember that without all the little people, the big people would have no one to relay their traffic to! No man is unimportant in NTS! No man is all-important, either. It's one big team doing a public service.

Traffic handling is surely something worth looking into. Not only can you perform a public service, you can also better yourself in one way or another as well. Don't think that you cannot be used if you don't have traffic; that's not true. NTS needs stations *from* everywhere to take traffic *to* everywhere. There is nothing preventing anyone from turning on his rig and checking into NTS. ■

The Third Hand

-- how many times?

Harry J. Miller

Sarasota FL 33580

When you're soldering small components, it can be a job to hold them, the soldering iron or gun, and the solder. The easy way is with a vise made with two spring-type clothespins.

Cut one leg shorter than the other, and then use small brads to nail the longer ends to the side of a small wood block. Place the item within the jaws of the two clothespins while you solder. ■

Vehicle Security Systems

-- protect your rig

The theft of radio equipment and other such valuables from vehicles is a current problem that is getting more serious with every passing day. We are all concerned with this problem, and rightly so, because if someone's vehicle hasn't already been burglarized, the odds are that sooner or later it will. That may be a pessimistic statement, but we may as well face facts: More mobile ham rigs are being stolen today than were stolen a few years ago before the rise in popularity of CB radios. The reason, as we are all aware, is that ham rigs are sometimes mistaken for CB rigs and are ripped off just the same.

As a result of this problem, many hams are taking preventive measures to protect their valuable property. Some of these measures include engraving driver's license numbers both outside and inside the unit and installing a quick disconnect mount to allow the rig to be easily removed and stored in the trunk. In addition, borrowing an idea from the CB market, there are a few swivel antenna mounts on the market that allow VHF antennas to be folded into the trunk along with the transceiver.

These measures are worthwhile, but we can always go one step further and include some type of security system as additional insurance against unwanted intrusion. Granted, if someone wants to break into a vehicle, nothing can really prevent him. However, if a security system in the vehicle goes off making some loud noises, most rip-off artists will usually run for cover, particularly if the attempted burglary is in an area where an alarm will draw a lot of attention, such as parking lots and busy streets.

The subject of building an electronic security system is not necessarily a new one, but there are new and unique ways such a system can be designed and built. This article describes a solid state security system designed around simple CMOS NOR gates for the ultimate in flexibility and reliability.

General Requirements of a Security System

Most of the commercial intrusion alarms on the market today generally fall into one of two categories:
1. Inexpensive alarms with an external key switch and no time delays, and
2. More expensive "electronic" alarms with exit/entry time delays and no external key switch.

The first (which I will refer to as key switch alarms), while being low in cost, are sometimes ineffective because of the visible external key switch which tips off the rip-off artist. He will usually do one of two things. He will reach under the battery compartment from beneath the vehicle and cut the battery cable, which disables the alarm. Or he can break the window, climb in, and make off with your rig without opening the door or setting off the alarm.

On the other extreme, the electronic systems with exit and entry delays have no visible key switch to tip off the burglar. This type is usually very effective because of the element of surprise,

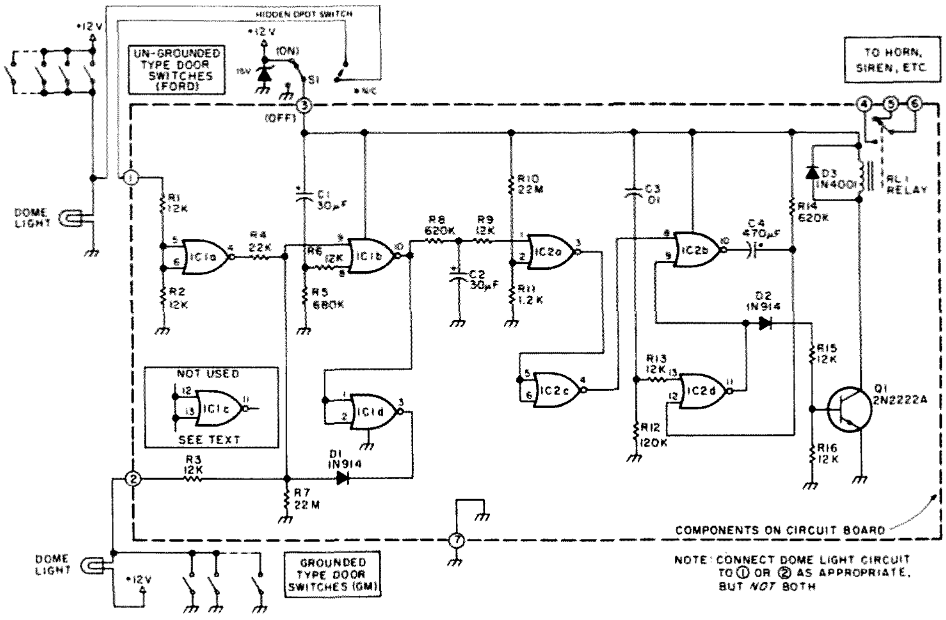

Fig. 1. Schematic diagram.

but can be expensive to purchase. In fact, the high cost of some of these sophisticated alarms has kept many hams from having the kind of protection they really need.

One solution to this problem is to build your own electronic system, thus keeping the cost low and protection high. Some of the features that an electronic alarm system should have are as follows:

1. Be able to operate over a wide voltage range and withstand the harsh electrical environment of a car's electrical system.
2. Exit and entry time delays to eliminate the need for an external key switch. The alarm is to be activated from within the car, before leaving.
3. To comply with the laws in some states, the alarm should have an automatic shut-off feature to turn the alarm (horn, siren, etc.) off after five minutes of sounding.
4. There should be negligible power drain on the battery until the alarm is triggered by an intruder.
5. The alarm should be easy to build and install, in addition to being low in cost.
6. Once the alarm is triggered, the operation sequence should be automatic and not affected by subsequent opening or closing of doors.

The alarm described in this article meets the above requirements and uses only two CMOS integrated circuits.

How It Works

Referring to the diagram shown in Fig. 1, the heart of the alarm system is comprised of two CMOS CD4001 2-input quad NOR gates which provide the switching logic for the system. These devices can operate over a wide voltage range (+5 V to +15 V) and are ideal for automotive applications.

The first CD4001 provides the sensor interface, latching circuitry and exit/entry time delays. The second CD4001 provides the output (through a transistor relay switch), as well as an automatic shutdown time delay for the sounding device.

Two types of sensor inputs are provided: one for ungrounded door dome light switches usually found in Fords, and one for the grounded type door switches such as in General Motors cars. When the hidden switch within the vehicle is switched on, C1 begins charging through a 680k resistor to ground. However, until C1 is fully charged (about 15-20 seconds), pin 8 of IC1b is at a high logic state. Since the output of a NOR gate is low if either or both inputs are high, the output of IC1b will remain low for the duration of C1 charging and regardless of whether the door switches are opened or closed.

However, once C1 is fully charged, pin 8 of IC1b is low, and opening a door will cause pin 9 of IC1b to also become low. When this occurs, the output of IC1b becomes high and two additional things happen. C2 begins charging through the 680k (R8) resistor connected to the output (pin 10) of IC1b. This begins the entry time delay sequence. Also, since both input pins (1 and 2) of IC1d are also connected to pin 10 of IC1b, the output of IC1d (pin 3) switches to a low state, effectively grounding the cathode end of diode D1. When this happens, the input of IC1b is latched to a low state and will remain that way until the alarm is reset with the hidden switch. The alarm sequence will continue regardless of any subsequent

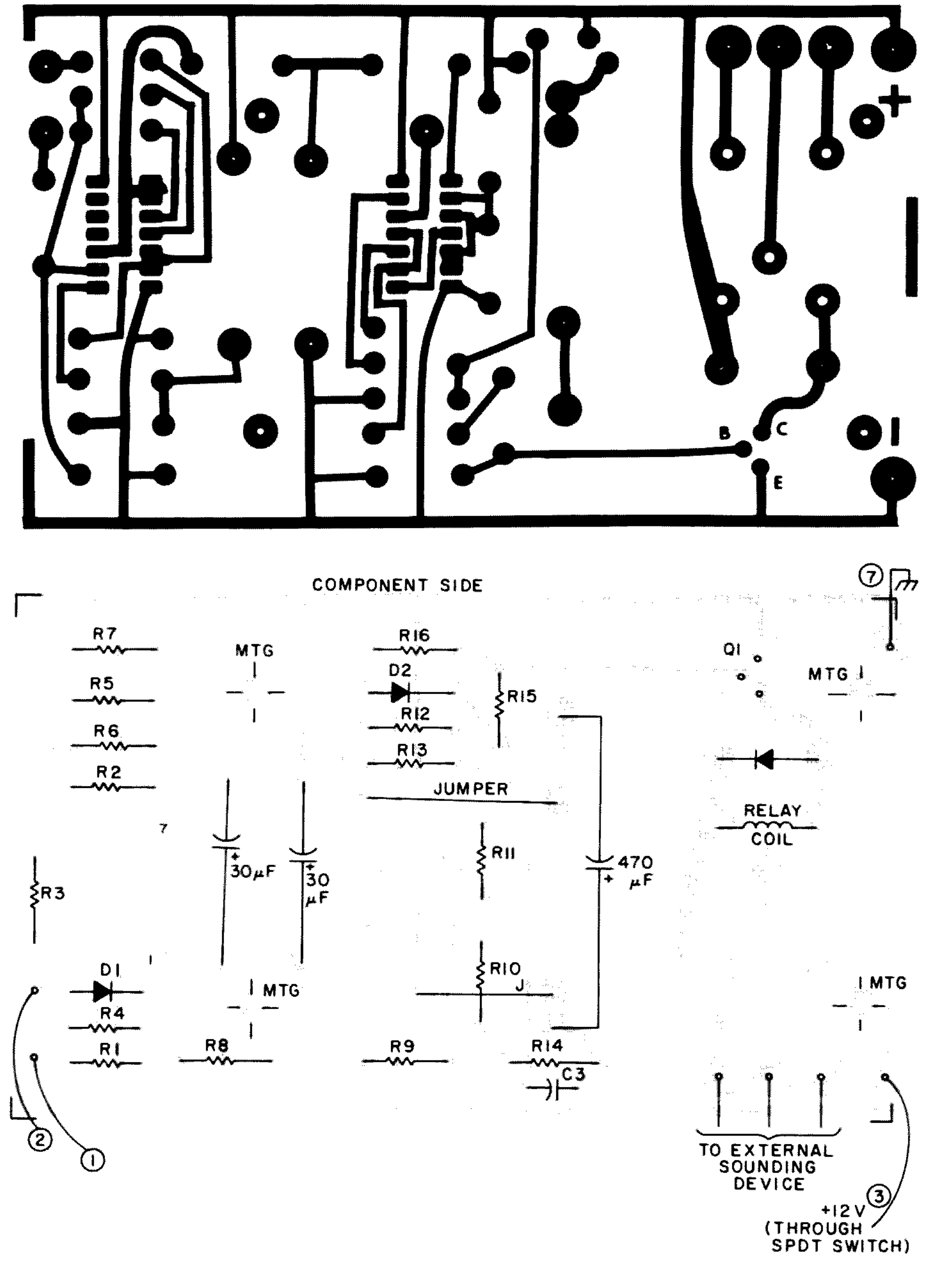

Fig. 2. Printed circuit board layout.

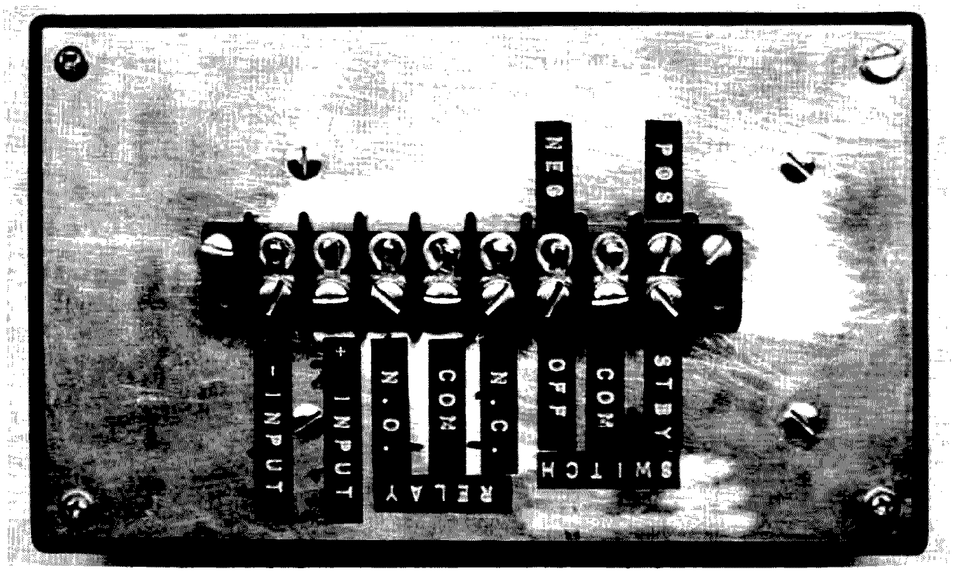

Front view of the security system control unit showing the eight-terminal barrier strip for external connections. Note that one row of screws has been removed and a small hole drilled through each terminal opening into the box. Leads were then brought through these access holes and soldered to small solder lugs for attachment to the remaining screws.

closing or opening of doors or sensors.

If the hidden switch is not reached in time (15-20 seconds), IC2d turns on the relay through Q1. This turns on the alarm sounding device, which remains on for the duration of the charging of C4 (approximately 4 to 5 minutes).

Construction Details

The security system may be built in a 6-1/4" x 3-3/4" x 2" plastic instrument available from most electronics parts suppliers. The layout is not particularly critical. Fig. 2 is an example of a typical PC layout for the circuit. The layout will easily fit into the above plastic case. Actually, the entire unit could be constructed much smaller than the example in this article by redesigning the PC layout for a more compact arrangement.

Although the circuit described works exceptionally well with the relay shown, you may want to substitute a 2N3055 power switching transistor in place of the relay. This will make the unit completely solid state and able to switch a load greater than the 3 Amps limitation of the relay contacts. With a slight redesign of the circuit board, the 2N3055 could be mounted in the same area previously occupied by the relay. If anyone is interested in this feature, drop me a self-addressed stamped envelope, and I'll send you a schematic diagram of the circuit.

If the actual load of the alarm sounding device is greater than 3 Amps, and you want to build the alarm with the internal relay, just use its contacts to control a heavy-duty relay at the load. In this way, the amount of current to be switched is limited only to the rating of the contacts at the source.

The printed circuit is etched from a 3" x 5" phenolic or epoxy glass blank, using standard practices. It [illegible] strongly recommended [illegible] IC sockets or molex pins [illegible] used for the two ICs. The obvious reason for this is to allow replacement of the ICs (and also to protect the sensitive input terminals from static electric charges during soldering).

Checkout and Installation

After the circuit board has been etched and wired, it's time for the initial checkout. First check out all connections, and, when you are satisfied there are no wiring errors, insert the CD4001s, avoiding any hand contact with their input pins. Then apply power to the circuit (-V to pin 7 and +V to pin 3 on the external terminal strip, temporarily eliminating the hidden SPDT switch to be used in the actual installation).

Next, with an ohmmeter, check the relay contacts. Pins 5 and 6 should indicate a closed circuit, and pins 6 and 4 should indicate an open circuit. After the initial entry delay period, use a jumper wire to momentarily connect input pin 1 to +V. This should start the alarm sequence, and after 20-30 seconds, you should hear the relay operate. Check the contacts with your ohmmeter. Pins 4 and 6 should remain closed for about 4-5 minutes and then reopen.

Next, remove power and short pin 3 to ground to

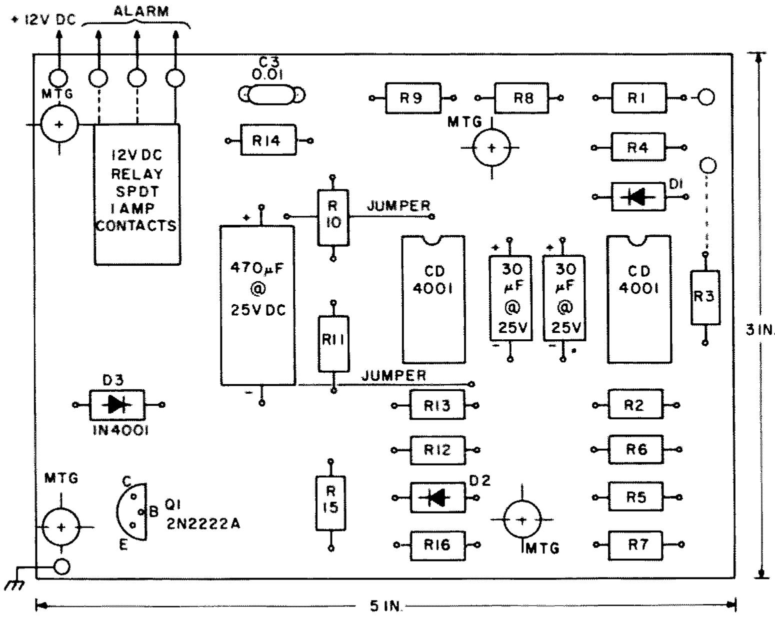

Fig. 3. Component placement.

discharge the electrolytics. This would be accomplished automatically when the unit is operated with the hidden SPDT switch (see the schematic diagram). Then restore power and wait for the initial exit time delay to reset. Repeat the previous check for input pin 3, but in this case momentarily connect the jumper from pin 3 to ground. After the entry time delay cycle completes, the output contacts of the relay should close and remain closed for 4-5 minutes. This completes the initial checkout and the unit is ready for installation into your car.

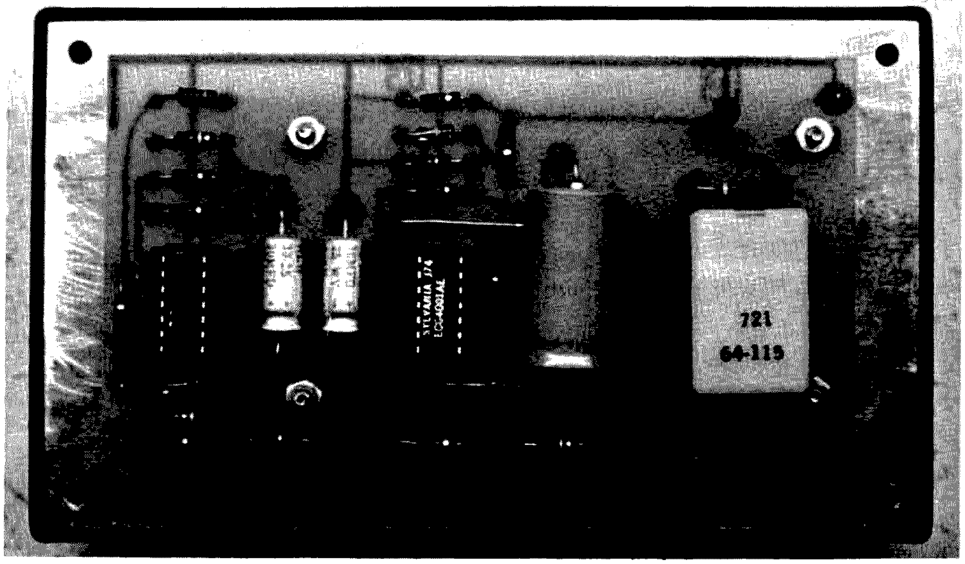
External connections are made through the barrier terminal strip as shown in Fig. 4. Power for the unit is derived from the car's fuse block, from a terminal that is not switched by the ignition switch.

The actual location for the unit may be anywhere in the vehicle that is away from view and preferably not easily reached. Also, the hidden switch should be installed at a convenient location that is not obvious to an intruder. The only remaining connection to be made is to the dome light circuit. Depending on your particular car, this connection may be to input pin 1 or 2 but not both. If your car uses ungrounded door switches, the connection will be to pin 1. (Note that this connection should be on the load side of the switch as shown on the schematic.) On the other hand, if your car uses grounded type door switches, input pin 2 should be used.

To complete the installation, you may want to add door switches to the two rear doors, trunk, and hood for total protection. As before, match the new door switches to your existing door switches and connect to the appropriate input terminal.

This security system should provide years of troublefree operation, and hopefully will someday foil the plans of any would-be intruder. If it prevents an unauthorized entry on just one occasion, it will have more than paid for itself. In fact, the cost to build this system is so reasonable that you may want to build another for your home, apartment or camper. Power drain is so negligible that it can be operated from lantern batteries for years. Just use NC magnetic reed switches in series from +V to the input of the unused IC1c. Then connect the output of this IC1c to input terminal 1 on the circuit board. As long as all switches are closed, the inputs are high and the output of IC1c is low. If a door is opened, the output of IC1c goes high and the normal alarm sequence is started.

As you can see, this circuit is very versatile and may be adapted to just about any alarm application. ■



This photograph shows a top view of the PC board with the components in place. External connections are made to the board through the terminal strip on the opposite side of the aluminum panel.

Fig. 1. Hexadecimal for IC-22S.

The recent arrival of Icom's new IC-22S has completely changed the 2 meter FM transceiver market. The most noted change is the decrease in cost, for a unit which has the features of a synthesizer. The IC-22S only requires you to program a diode matrix board for the common frequencies that you will be using with the 22 selector positions. This makes for very convenient operation, with an even greater advantage over a regular synthesized unit while in mobile use. We have been able to create the best of the crystal controlled rigs and the synthesized units, with a slight modification of the 22S.

The modification, which should cost only a little over $2.00, simply consists of making use of the 23rd position of the selector switch, with the addition of a miniature 8 position DIP switch. This will allow for programming this position at any time, for any unusual frequency that you desire, at any standard 15 kHz spacing. The location that was picked to mount the 8 position DIP switch was on the underside of the radio, between the matrix board and the front panel. This allows minimum wire length, convenience of operation, and very little modification to the unit.

The first item that is required is a small piece of vector or printed circuit board, approximately 1 3/8" by 1", to mount the switch on. The best source of this material might be one of your surplus computer boards from which you have removed a 16 pin integrated circuit. Due to the limited mounting space, this makes for an easier installation than using an IC socket and associated hardware.

Simply drill two #39 holes in the rear lip of the front panel to secure the printed circuit board. The right side of this PC material should be aligned with the position 19 of the matrix board to allow for ample mounting space. The first hole has already been drilled through the plastic portion, so it is only necessary to complete the hole through the metal portion. The second hole is drilled about 7/8" to the left. Countersink these holes to allow for installation of 2 #3 flat machine screws. Another piece of PC board material, 1-3/8" by 3/8", should be cut and drilled to be used as a shim (between the front panel lip and the PC material, which will have the switch mounted later). This will make the top of the switch block even with the cabinet cover assembly after it is reinstalled.

It will be necessary to cut a slot with the dimensions 5/16" by 7/8" parallel to the front of this cover to allow for activating the switches after the cover is reinstalled. Viewing this cover from the front of the rig, the slot should be located 9/16" from the front and 1½" from the right side. The next step is to

modify the matrix board by drilling 8 #60 holes in the right end of the matrix board, just to the left of the D0 through D7 markings on the board, making sure that they do not make contact with any of the conductive copper on the board. This will allow for the insertion of 8 diodes which will later be connected to a cable assembly, which will be connected to the 8 slide switches.

Mount the mini DIP switch to the PC board. Install 8 diodes with the anode end going through the new holes just drilled in the matrix board. Assemble a 3" 8 wire cable, using stranded wire to avoid breakage. It is best to use a color coded arrangement, as you will need to keep the wires in order for wiring into the switches. If coded wire is not available, it would be advisable to run one wire at a time, starting with diode D0 going to the right-hand-most switch. Continue in sequence until all positions are wired. The next modification is to run a wire from the unused 23rd position of the selector switch to a common point of all of the 8 slide switches. Test for broken connections and solder bridges. Mount the matrix board and the switch unit with the necessary screws.

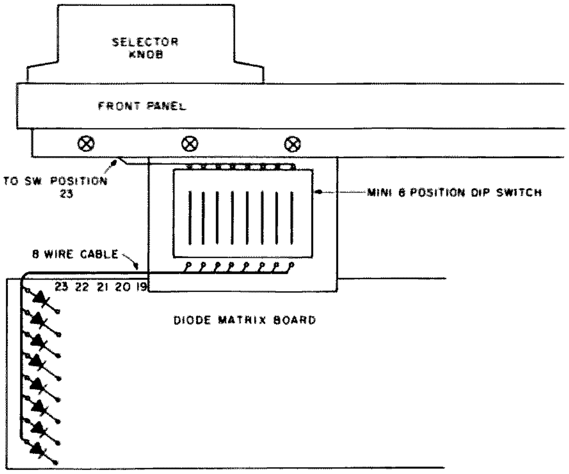

Fig. 2.

A note should be made at this time on the actual programming of the switches. Anyone who is familiar with the hexadecimal system will have no problem in remembering how to program the unit. The layout is two hex bytes as follows: 00 to FF, which you can lay out as 8421 8421. An example: To program 146.55, you would need hex 90, or 1001 0000 in the switches from left to right. As another example, 146.94 would equal hex AA, or 1010 1010 in the switches. After learning a couple of these reference frequencies, simply remember that each value of hex one equals a change of 15 kHz.

Another modification that can be done is use the small version of the hex (base 16) thumbwheel switches and mount 2 of them in the cover near the speaker, as there is sufficient room at that point. Others have run a cable to the accessory plug and used an external switch assembly. You could also use the octal thumbwheel switches, which are easier to obtain, but 3 are needed. Some people find it more confusing using the octal system, as it is more difficult to remember the frequencies.

Any of the above provides for a very practical synthesized unit at a reasonable cost. ■

The Missing Length

-- phantom IC-22S channel

Even in an area where repeaters are few and far between, such as Maine, it was easy to fill all 22 channels of the Icom 22S. When you start adding area repeater frequencies, a few essential simplex channels, and attempt to cover yourself for those trips to other locations, it is very easy to run out of available channels and wish you had "just one more."

While recently pondering the replacement of the final in my Icom only two days out of warranty, I noticed that the 22 channel diode matrix board had positions for *23* channels. On closer inspection it became apparent that the 23rd channel on the matrix board was not a mistake, but a bona fide operable set of holes which I could program to get that extra channel.

There was no wire connected to the 23rd position on the matrix, so I quickly scrutinized the rotary channel selector and found that one pin following channel 22 was empty. At this point it crossed my mind that this could be a trap — there must have been some reason why Icom did not wire in the 23rd channel, and I was overlooking something very obvious. I have been known to do that once or twice. Thinking that the unused connection might be grounded or in some other way be unusable, I checked the unused pin and several other connection points for anything that looked the least bit unusual. Nothing found.

Finally throwing caution to the wind and dedicated to making some mistake, I ran a small gauge wire from the 23rd row on the diode matrix to the empty pin on the rotary switch. Success! Now, when I select the dot following channel 22, I have access to yet another essential frequency. Frankly, I have no idea why Icom deleted channel 23 when building the 22S, but as long as I am able to expand my capabilities, I'm happy.

Now, if I had just one more channel . . . ■

Design A Circuit Designer!

-- with special plug-in boards

Many amateurs are aware by now of the component plug-in boards that allow the test assembly of a circuit without soldering. These boards are produced by a number of manufacturers and utilized as the heart of various "circuit designer" pieces of equipment.

This article describes the use of such boards in a circuitry "test bed" configuration that is particularly well-suited to use by radio amateurs. The test bed contains many features found in the more elaborate, and expensive, "circuit designer" pieces of equipment. But the cost can be kept low, with the main cost being that only for the main plug-in component boards. Also, some measurements were made on the boards which might be of interest to amateurs who want to experiment with rf as well as with audio circuits.

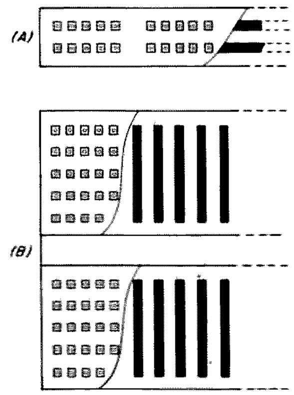

Fig. 1. This drawing shows how the internal metal binding strips are used to interconnect the component plug-in tie points on a bus strip (a) and a circuit socket (b).

For those not acquainted with the plug-in boards, their basic makeup is shown in Fig. 1. Two basic boards are available – a circuit socket board and a bus strip board. Both come in various lengths. The circuit board has five tie points, which are all interconnected vertically on either side of a gap in the middle of the board. The gap is spaced so an IC or transistor can straddle it and plug directly into the board. The bus strip boards have two rows of interconnected tie points running horizontally, but grouped in clusters of 5 tie points each. One can, if desired, break the interconnection of the groups of 5 tie points running horizontally so as to produce 4 rows of tie points. Or, one can isolate one or more clusters of tie points and permanently connect them to input/output devices. Other components such as resistors and capacitors plug directly into the boards, and interconnections are made with #22 hookup wire plugged into the boards.

Complete, rather elaborate radio receivers have been test-built using enough of these boards, but for the average amateur who builds a multiple transistor/IC amplifier, keyer, filter, speech processing device, etc., 3 boards only will suffice. The boards used in the example for this article are the Continental Specialties QT-595 circuit board, which is 6½ inches long and sells for $12.50, and two matching QT-59B bus strips, which sell for $2.50 each.

The boards are placed on top and towards one side of a 7" x 11" x 2" chassis. There is about 5/16" spacing between the circuit boards and the bus strips, but this is just an arbitrary spacing. The rest of the chassis has mounted on it various connectors for input/output connections, power supplies for linear and TTL ICs, metering provisions, and a built-in loudspeaker. Also, room has been left to the left of the circuit board to include a built-in rf or af signal generator for a really complete "circuit designer" configuration.

By carefully examining the arrangement shown in Fig. 2, one can envision how the various terminal posts and connectors are arranged. This arrangement is a matter of personal preference, of course, but the arrangement shown has proved to be very convenient. Basically, two input and two output BNC sockets are used, and wired to binding posts near the circuit board. Two grounding binding posts are on either side of the circuit board near the lower bus strip. The -V binding post is centered below the lower bus strip. The two meter binding posts are to the left of the meter, and next to them are two more posts – one for a fixed +5 volt output and the other for the +V output. PL-59 type jacks are associated with the loudspeaker and with one input binding post for the quick connection of microphones and headphones using PL-59 plugs.

Three power supplies are available in the unit, but only *one* transformer, a 24 volt CT unit, is used. The 5 volt supply is regulated with an LM309K. The +V and -V supplies are regulated by zener diodes in a conventional regulator circuit. Either ±6 or ±12 volt outputs can be switch-selected. All the components for the power supply, except the transformer, are assembled on a piece of perforated board stock and mounted in any convenient location inside the chassis.

The circuit and bus strip boards come with a paper backing. If this is removed, one can readily see, for instance, how the tie points are interconnected on the bus strips and how they may be further broken down if desired. Since the circuit board would be used for rf circuit testing, it was thought best to better insulate the boards from the chassis. If available, the best thing would be to replace the paper backing with teflon tape. But embossing tape of the Dymo variety will also work fine.

Audio circuits and digital circuits can be pretty well "wired up" (that is, plugged into the circuit), as shown on

a schematic. The bus strip boards are used to run the ground, +V, and -V lines around the top and bottom of the circuit board. Rf circuits require a little more care in layout, since one must keep in mind the stray capacitances that exist around the boards. Bypassing can also be a problem, since it must be made with leads as short as possible to be effective. As regards stray capacitances, measurements showed the average insulated binding post will show about 7 pF to ground. A bus strip run (10 of the 5 clustered tie points) will show about 20 pF to ground. One of the 5 vertical tie points (on either side of the center channel of the circuit board) will show 2-3 pF to ground. Parallel running tie point clusters on the circuit board show about 2 pF between them. All these values are not too bad and can be lived with for many HF circuits, although VHF circuits would generally be impossible to lay out. A greater problem with rf circuits is good bypassing. The solution to this might lie with placing a number of miniature ground lugs in the space between the bus strips and circuit board, and placing bypass capacitors between the circuit board tie points and the ground lugs as necessary for any given circuit.

Two banana plug sockets are installed below the lower bus strip on either side of the -V terminal. These are for the mounting of a plug in the front panel. The panel is not shown, but it is just a flat piece of aluminum stock drilled/punched randomly with cutouts to accommodate switches and potentiometers of various sizes.

In any case, for someone who likes to do any sort of circuit experimenting, the plug-in boards are highly recommended. Parts can be reused many times and one avoids those soldered-up, three dimensional, experimental lash-ups which look like modern art gone astray. ■

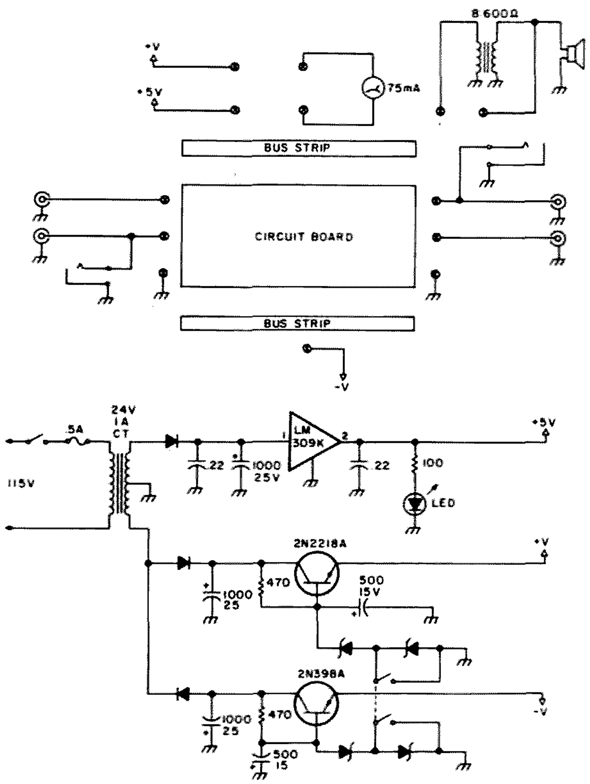

Fig. 2. Arrangement of the binding posts around the plug-in boards and the triple voltage power supply. The zeners are 6.2 volt types. By shorting out the lower zener, a selectable output of ±6 or ±12 volts is obtained.

Sensitive Meters Saved

A simple overvoltage protection circuit can be built to not only protect a milliammeter (used as a voltmeter with a series resistor), but also provide a visual indication of the fact that the meter is in the "off scale" region.

For normal operation, Z1 (a 10 volt zener) has less than 10 volts across it, and R1 and R2 (in series) simply function as a 20 volt meter multiplier for the 0-1 mA meter. When E1 gets to 20 volts, Z1 conducts and turns on Q1, which draws current through R3 and the LED. The LED gives a visual indication of the overvoltage condition.

The zener Z1 is one of a series of Motorola diodes that have particularly sharp knees at low current. Other zeners will work, of course, but the demarcation between "normal" and "overvoltage" will be less well defined. The values of R1, R2, R3 and the breakdown voltage of Z1 may be changed to suit one's particular voltage range. ■

Big Bust In Amarillo

-- bootlegger nabbed!

Do not pass "GO." Do not collect $200. In fact, Jim Krueger, go directly to jail.

It may sound like a game of Monopoly, but, in Amarillo, Texas, it was more like cops and robbers on July 7, 1977. Four hams nailed James Krueger, infamous haunter of repeaters and county jails from coast to coast. Krueger, known by more than a dozen different aliases and a number of bootlegged or "borrowed" calls, is now held on a federal charge, without bond, in the Potter County Jail, as a result of the actions of Joe Bethancourt WA7TUM/5, his wife, Mary Alice, Jim Wilhite W5RXC, Scott McDowell WB5JJN, Joe Cowen WA5TUM, and his fiancée, Malinda Lyles.

Cowen, president of the Amarillo Repeater Society, and McDowell, repeater trustee, along with society technical committee heads, Wilhite and Bethancourt, had been on Krueger's trail at various times since he first appeared in the Amarillo area a year ago. Then he was using a legitimate call, WB9MRA, which he "stole" from a duly licensed Indiana ham.

But three weeks of bogus operation in June and July using a nonexistent call, WD7AAB, finally led to his arrest. It had been a game of hide and seek with DF loops, but quick-triggered Krueger was always on the move and kept his transmissions short. Most Amarillo amateurs played the game of chatting with Krueger, knowing all along that the committee of four was out chasing him.

Hams had first become suspicious of Krueger a year ago because of his unorthodox repeater habits – "WB9MRA, requests the patch" – at which time he would key up the touchtone autopatch access.

His old, white school bus, laden with CB slogans, antennas, and advertising for CB repair, was seen by Cowen last year, before it was known that he was illegally using another amateur's call. But Krueger became wise to the situation and disappeared last summer, before he could be apprehended.

During summer months, Krueger travels Interstate 40, working truck stops. This year he was recognized, by the unmistakable Indiana twang of his voice and his well-known repeater habits, even though he was using the new call. One call to the FCC established that it was a fictitious set of numbers and letters. WD7AAB just didn't exist. A vehicle similar to his was spotted briefly by another local ham, John Gifford W5SYB, who immediately contacted Cowen. Cowen later saw the bus in the parking lot of a movie theater in Amarillo.

"I had gone to see 'Star Wars,' but I never made it," he said. Cowen and his fiancée, Malinda, saw a crowd in front of the theater and learned a projector had broken and was being repaired.

"That discouraged us," he said, "and I started to drive away, and Malinda saw the bus." It was vacant and parked. But, it was the same bus driven in Amarillo last year by Krueger.

Cowen called the other three hams, by telephone, from a nearby store, knowing that Krueger carried a pocket scanner. McDowell, a dispatcher for the Texas Department of Public Safety, put local highway patrolmen on standby, and joined the stakeout crew – Cowen, Bethancourt, Wilhite, Miss Lyles, and three vehicles fitted with UHF gear on a commercial frequency for coordination without detection.

The stakeout started at 6:50 pm, and, finally at about 10:45 pm, Krueger came out of the theater and entered the bus. Before his exit, the hams, knowing from past experience that the bus had equipment to monitor 2 meter and law enforcement frequencies, had set up a communications system using Bethancourt's wife, Mary Alice, who was at home.

"We used the UHF gear to communicate with Mary Alice," Cowen said. "Then she'd talk to DPS holding on an open phone line."

Officers then made arrangements to stop the bus on Interstate 40, after it was trailed in James Bond fashion throughout the city by the four hams coordinating through Mrs. Bethancourt.

"We were just plain lucky," Cowen said, "that it turned out that Krueger was wanted by the FBI for unlawful flight to avoid prosecution, a fact that could not be confirmed until officers had learned his date of birth from the 'driver's license check stop' made by the highway patrolman.

"We knew that he was arrested in Indiana last year and jailed for dealing in stolen CB equipment," Cowen added, "and this year we got highway patrol cooperation because the registration tag on the bus did not fit the vehicle, according to information Scott McDowell was able to get out of Arizona, its state of registry."

Because of the mismatch of license tag to bus, Texas troopers had "just cause" to stop the thing and investigate.

"We hoped that some of the CB radios, or perhaps the Icom 2 meter gear he was using, would turn out to be stolen," Cowen said. "We had

tried last year and this year to get the FCC Field Enforcement Team interested. It seems that they could not have cared less, and we knew if we were to get Krueger off the air, it would have to be done on other charges, due to the lack of interest demonstrated by the FCC and the American Radio Relay League.

"I wrote the ARRL and the FCC last year about Krueger, and so did the legitimate holder of WB9MRA. As far as I know, neither of us even got an answer. I know I didn't," emphasized Cowen.

"However," Cowen stressed, "I think we may get some action this year from the FCC, for I hand-carried a written request to the FCC to investigate the situation to Texas Congressman Jack Hightower. We have tape recorded evidence against Krueger, and, by his own admission to the highway patrolman who stopped him and asked to see his amateur radio license, we know he is not a ham.

Ham hunters who nailed bootlegging operator James Krueger are (left to right) Joe Cowen WA5TUM, Malinda Lyles, Mary Alice Bethancourt, and Joe Bethancourt WA7TUM/5. Kneeling are (left) Jim Wilhite W5RXC and (right) Scott McDowell WB5JJN. Hams and two of their ladies are shown around a Dodge Ramcharger, one of the vehicles used to track the bootlegger, who is now in jail awaiting federal prosecution.

"Even the FBI has egg on its face after this deal," Cowen added. "Scott McDowell also phoned the local FBI Resident Agent to tell him that we were staking out Krueger, because he was in violation of federal law due to his illegal amateur radio operation. That agent didn't have much to say when he was phoned again later the same evening by Scott to inform him that he should appear at the Amarillo DPS office to pick up his prisoner. The agent was completely uninterested in Krueger when we wanted him for violation of communication laws, but his interest picked up somewhat when he learned that we apprehended a fugitive under federal warrant."

"Some of the radios in the bus have had serial numbers ground off, and it is my understanding that checks are being made on all confiscated equipment," Cowen said.

"We realize that Amarillo is a long haul from the nearest FCC office," he added, "but we feel that this case warrants further investigation, so hams will never again be bothered by James Krueger. We know the FCC is on our side, but at some point it is necessary to either enforce the rules we have or forget them altogether. If we forget them, however, then we have lost amateur radio to the money-hungry EIA, with its lucrative CB industry, and the amateur frequencies will rot away to the tripe now found on 11 meters. I hate to see this happen, but we hams are powerless, it seems, to legally enforce the rules, and, without the FCC's help, we are completely vulnerable to any CB freak who has the bread to buy a radio. If Krueger had not been wanted on other charges, I'm afraid he'd still be on 2 meters." ■

Right Way, Wrong Way, Navy Way

-- or the 73 way

Learning the code can be approached in a systematic and rewarding way. Like the title suggests, there is a right way to go about it and there is a wrong way. And when you are finished arguing about these, there's the Navy way.

As for my credentials, I attended the Naval Radio Communications School some years ago, and there in the short period of three months became a "35-word-per-minute man." Subsequently, on board ship and with a year of radio watches behind me, I copied "px" (press wireless) with ease at 50 wpm while covering the International Calling Frequency with the other ear. No one, of course, writes with a stick (pencil) at that speed. We learned to copy the code directly onto a typewriter with a special telegraphic keyboard with almost identical upper and lower cases.

There are other ways of communicating intelligence by code. I learned land line telegraphy and blinking light as well. Land line takes a somewhat different code, the true Morse code, which is an alphanumerical setup, with five clicks for a "p" and spaces between the elements of a few characters. It is received with a sounder, a clicker instead of the beeper that hams are familiar with. Another code method is machine tracing of the impulses on a strip of paper (either by offset or broken trace) and then sight reading the result like an old 1929 Wall Street tycoon with his ticker tape.

The ham type code is known as the International Morse alphabet, adapted from the true Morse, the better to hear the beeping sounds from a radio receiver with.

Some persons have a knack for the code, like a drummer has rhythm. Others will never learn it, like some people can't carry a tune in a satchel. There is a psychological synapse in the brain that can distinguish the difference between a short beep and a longer beep, which we shall henceforth call "dit" and "dah," respectively. Some people's heredity simply did not include the required synapse, and to these a dit is exactly as long as a dah and spaces between do not exist. The good code man finds this hard to believe, because code comes so easily for him, but the poor guy whom nature forgot can well believe it. More about this aspiring ham later.

The Navy taught its operators to send with a hand key. "Bugs" were verboten until we could handle 18 wpm with the hand key with ease. We had to take a test before a gimlet eyed old shipboard operator before we got our "bug ticket." The test was first on our hand-key sending ability and, secondly, on our ease and familiarity with the semi-automatic T. L. McElroy Vibroplex, the bug. There was good reason for all this caution — listen to any code ham band, and you'll see why. The lives of many good men depended on the accuracy of sending and receiving the code on board ship. There was no phone wireless at one time, remember? And even when it first came into shipboard use, phone was far from dependable. Navy operators were taught to send clearly, at a speed no greater than could be received by the operator at the other end. Demerit points were accumulated for repeating portions of messages, for corrections, etc. The idea was to send so clearly and distinctly that the receiving operator got a perfect message the first time.

When I took my ham exam, some years after leaving the Navy, I petitioned the FCC examiner to use the typewriter instead of a pencil for receiving. He, though surprised and not quite sure the regulations permitted, agreed. He had a code sending machine that he used for making the test as fair as possible which he could set at any speed up to umpteen wpm. After I had done the required minimum speed test with obvious ease and accuracy, he asked me if I'd care to boost the rate. He advanced the speed about 10 wpm each minute, and at 55 wpm I began to make errors and to falter. That was the first time I knew with accuracy, after all my years of shipboard operating, just what my code ceiling was. Needless to say, I passed my ham ticket code exam the first time and, later, the ARRL 35 wpm certificate as well, thanks to Uncle Sam's Navy. I mention this for good reason.

There is an aspect of learning to send and receive the code that resembles a stairway landing: plateaus. You begin with individual characters and advance to recognition of character combinations. This recognition is at first a conscious act. You strive to make sense from the sounds and silences, and suddenly sense comes through. Instead of "dit dah stands for A," you suddenly recognize that "dit dah *is* A." There is a very important difference here, make no mistake about it! Then when you drop the "is" and *dit dah becomes A in truth within your consciousness,* you have ceased to translate, and are "thinking in code." That's important! It's the whole ball of wax.

I don't mean to make it all sound easy. Learning the code takes a lot of application of the seat of the pants to the chair, hard work and perseverance. You are learning a new language, just as surely as though you were studying Spanish, German, or Parsi. If you would study the science of communication, try Norbert Weiner's *Cybernetics.* You'll come out a better all around ham for having tackled it.

I contend that most of the trouble people have learning to send and receive code is with the teacher, yourself included when self-taught. Vital to your success is a positive mental attitude. One of the first mistakes every teacher makes is to teach you the code alphabet. Don't do it! At least, don't do it that way.

Get hold of a first grade reader and start at page one, letter one, word one. Each letter you don't know the Morse character for, look it up on a handy chart, and convert it to the phonetic: "B" = *dah dit dit dit.* Say it out loud: *dah dit dit dit.* Hear it. Send it on your hand key (stay away from semiautomatics and automatics until you can send fast and comfortably well with the hand key.) Do not, ever, say: *dash dot dot dot.* That is not what you hear coming out of the speaker. You are learning to recognize code by sound, not sight (at this point at any rate).

By taking the letters as they come in a child's reader, you will be learning the code as it was meant to be learned by the inventor who was a much smarter man that he is generally given credit for. Note that the most frequently used letter in the English alphabet is "E". Note its counterpart in Morse: *dit.* Yes, he did take frequency of letters into consideration, and the International Morse improved upon this somewhat. And that's the way you should learn to recognize the Morse language, most frequently used letters first. You won't have to worry about how often you have to refer to the code chart – your natural laziness will soon commit the letters and their Morse counterparts to memory rather than go through the extra work of referring to the chart each time! It will come surprisingly naturally if you simply do it the Navy Way!

Now as you become better and better acquainted with the sounds, and the sounds become the letters, a point will be reached when you will suddenly find yourself recognizing two and three letter combinations. They will sound like a new Morse character that isn't in the alphabet: *dah, ditty ditty, dit*: the. The silences will take their places in the character if you are being careful not to slur in your sending and are making each character distinctly and with its spaces where they are intended and the length they are intended to have. You will be developing your ear, and you will be walking on the second plateau before you even realize it was a struggle to get there!

So you keep on going, and, after you have gone completely through the primer reader, do it again and then a third time. Now you will probably be ready to take on a standard book, say a radio theory handbook, or a page of *73 Magazine.* Don't skip over the numerals. You've got to learn them now, and they are no more difficult than the letters. Do them the same way, by referring to the chart when you hit one you don't quite remember. Get with it and before long you will recognize a series of two and three letter words all as one character! You will have reached the leading edge of the third plateau. Keep pushing, keep practicing, and you'll be walking on third level with ease before you realize it was a tough nut to crack. When you do, you'll be receiving 15 wpm or better!

After that it's practice, practice, practice. There's another plateau at about 25 wpm, and another around 35 to 40. Once these humps are cleared and become comfortable, copying behind begins to sneak up on you, and your elation will know no bounds. Your code will have become a second language, just as surely as Hindi, Chinese or Russian. I once shared the radio shack with a guy who copied from 20 to 30 words behind! You can't possibly keep up with individual characters at that speed. The reason has to do with learning to type and its distinctive plateaus, word-combinations, etc.

There is a way of sending Morse with a hand key that is unbeatable for clarity and ease. You can send all day without getting tired if you will learn this method from the beginning: Raise your wrist slightly with each downward motion of the hand on the key, like Liberace on the piano only not quite so carried away. Don't grasp the key with a death grip; treat it reverently, lightly, caressingly. That way your muscles will remain almost relaxed. (Yes, I know that raising your wrist feels absolutely wrong at first. But persevere, and you'll never regret it.)

It takes a lot of hard work and determination to master the code, but I am certain that too many potentially good hams make a hard, hard, bitter job out of it when really it's not that hard at all. It's simply a matter of starting out on the right foot – wups! Careful! You'll be accused soon enough of sending with your left foot!

And when you've been at it for a few years, and the birds and bedsprings begin talking to you in Morse, it's time for a vacation into the phone bands! Many a crack Navy op ended his radio career in a padded cell – there's a certain hazard attached to daily, year in and year out high speed code work.

What's tops in speed? Well, there's another little quirk of the human grey matter that blends a rhythm into a solid roar above a certain threshold. Even the best signalman begins to lose his differentiation of blinking lights at about 12 to 15 wpm. If he didn't he'd never be able to appreciate the movies or television. Same thing with code by ear. After some level around 50 to 75 wpm, individuals will find it's time to let the computer handle it.

There are dozens of little hints and kinks that can be passed along by old radio ops. For instance, you've got to push yourself to copy at a speed faster than is comfortable for you at any given time in your learning period. If you don't, you'll top out at a very low speed. It also means that you have to expect to make errors. Don't sweat it; let the errors fall where they may as you are climbing the speed ladder. When you have reached the level beyond which you don't feel the effort is worth the use to which you'll put the ability gained thereby, settle down at that speed and begin to perfect your accuracy. Keep away from swinging your sending. Another hint – if you make a mistake, don't go back over it. Keep on going with what you are copying. Trying to correct an error only causes you to miss what's coming. After you have learned to

copy behind the signal, there's plenty of time to correct minor errors.

Another hint – learn to receive on a typewriter, right from the beginning. There's a much better linkup between the code, your brain, and a typewriter key than between the brain and a pencil.

And after all this, if you try and try and pretty soon six months rolls around (at 2 hours a day) and you haven't passed 5 wpm, ask for help from a psychologist. It's just possible you are one of the unfortunate few whose synapses never quite got together for that particular mental function. Then do some letter writing. Petition the FCC to let such bona fide proven-by-a-psychologist handicapped persons pass the test by reading written dot dashes from a moving tape. Because, chances are, even though you can't hear the difference in character lengths, if you are sighted you can learn to read the difference as fast as you and I can read this printed page! Having known guys who could, whose job was to handle the automatic code printer in the radio shack, I'd say we have reached a point in our ham evolution where there's room for this particular exception.

Therefore, let nothing you dismay. You, too, can learn the code. As long as the majority of hams persist in maintaining the code test requirement for licensing, go along with them and show them you've got what it takes to pass their silly old test. And who knows, maybe it's not so silly after all? Suppose, for instance, you were suddenly stranded on a desert island, and all you had to signal for help with was a simple, keyed transistor oscillator you whipped together out of a pocket radio? Once you learn the code, you'll be surprised at how much fun you can have with it, and, at infrequent times, how *valuable* it is to you! ■

Living With the Family Ham

-- planning births, etc.

In many situations a ham marries a non-ham. Realizing that there is a scarcity of information available on how to cope as a non-ham in a ham world, I have compiled the following information dedicated to greater harmony in the lives of hams and their spouses.

1. Do learn the radio vocabulary.
– PTT and CW are not real estate agencies.
– XYL is not the abbreviation for xylophone.
– 73s and 88s are not just lock combinations.
– DX is not just a brand of gasoline.

2. Remain calm while as many as 5 antennas are installed on the roof. Describing to a stranger that you live in the house with 5 antennas leaves less chance for misunderstanding than describing a house with blue shutters.

3. Don't panic when the utility room gets transformed into a ham shack.

4. Plan to serve meals at times that do not interfere with radio nets.

5. If possible, try to schedule the birth of children in midweek so as not to interfere with hamfests.

6. Don't get upset if your spouse cannot coordinate 2 articles of clothing in the closet, but he is able to spot a new transceiver in a store window from across the street.

7. Don't get alarmed if the side is cut out of the broom closet to make way for a transceiver installation.

8. Even if they do just look like funny post cards to you, do not throw away QSL cards.

9. Do your homework. Have ready for curious friends and grocery bag boys at a moment's notice clear and logical answers to the following questions:
 a. Why do you have those funny license plates on your car?
 b. What kind of CB is that?
 c. Can you hear police calls on that?
 d. How far away can you talk to people?
 e. Can you talk to my friend in Guatemala (or Peru, or Liberia, etc.)?

10. Learn to reassure the neighbors when they ask if being a MARS member means you report the activities of the neighbors to the FBI.

11. If possible, study radio code and theory for your own license. Never under any circumstances comment that the code sounds to you like a confused woodpecker.

12. Relax and enjoy the benefits of your spouse's hobby. It does, after all, keep him (or her) home much more and is usually less dangerous than auto racing or scuba diving.

After almost 6 years of marriage to a ham, I took the test. In October, 1976, I was licensed as WA4WZL. ■

Add Jazz To Your Tempo

-- with a few simple mods

Ronald R. Groshans WB8ZBJ
PO Box 727
Niles MI 49120

Microphone with clip installed.

I have been an amateur radio operator for about a year and have had to start on a financial shoestring. My first piece of equipment was a Tempo fmh HT. As my only means of communicating with my fellow hams, the HT went a lot of places with me. I soon discovered that the handie-talkie was not so handy as it was on the road. I tried hooking a carrying strap to the two provided eyelets, and this, too, proved unsatisfactory. I then put on my thinking cap in earnest.

I knew Motorola made a wide variety of HTs. I dug out my Motorola wish book (commonly called a catalog) and started my search for a better means of carrying my HT.

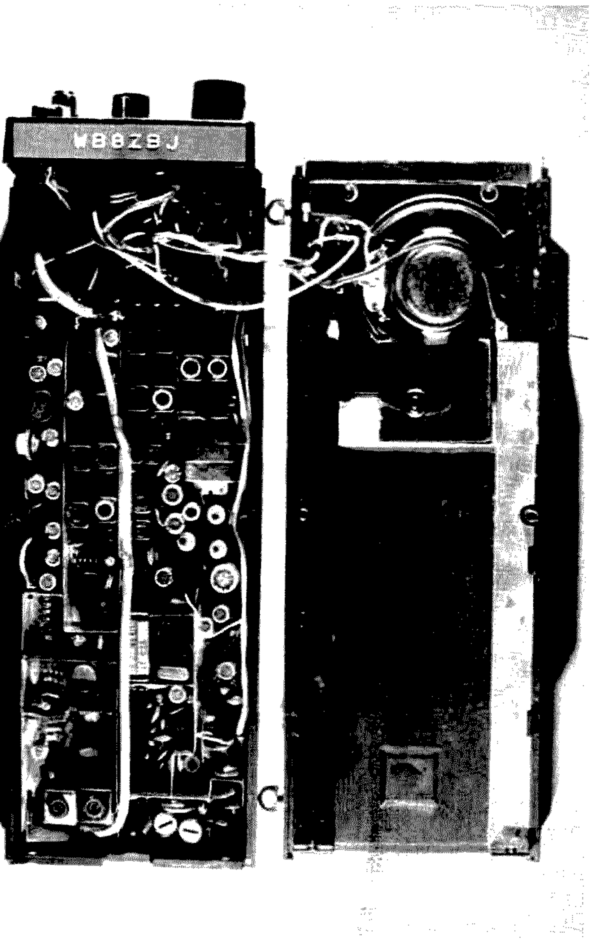
I discovered that there were two ways available to carry an HT in comfort. One way was by means of a case which attached to the belt. To use the HT one simply lifted it out of the case. Second was by means of a belt clip, the belt clip being permanently affixed to the unit. This second method I liked for two reasons; one, it was more secure, and, two, it turned out to be less expensive.

Having solved the problem of how to carry my HT, I started to work on the idea of a hand-held microphone accessory. This turned out to be more time-consuming than the belt clip. Therefore, since it would take time to work everything out on my microphone accessory, I decided to go ahead and put the belt clip on.

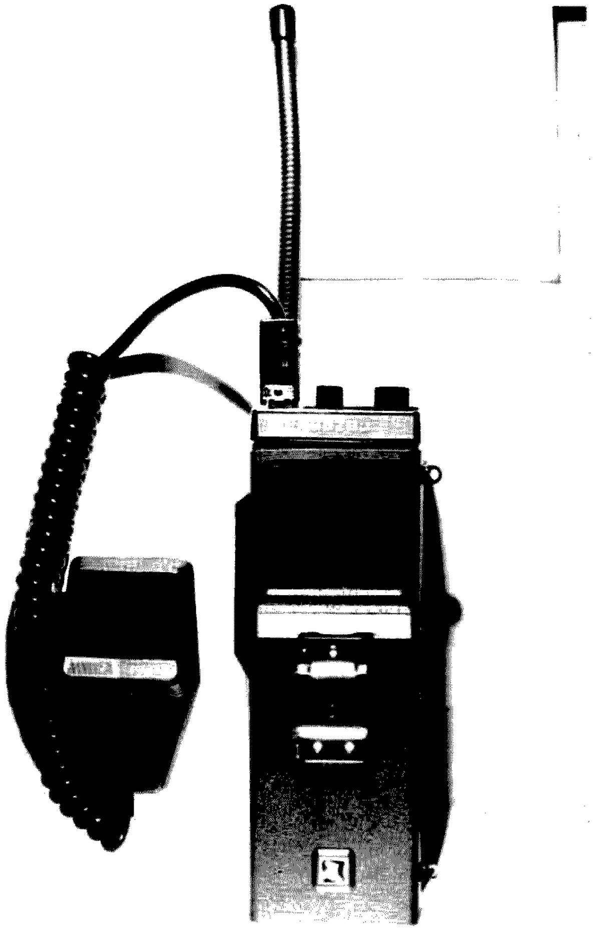
I went to a local Motorola parts sales and repair dealer and ordered what I needed. I placed an order for one belt clip, one fiber adhesive insulator, two screws, and one metal backing plate. The entire order came to a whopping grand total of $3.67. The Motorola dealer did not happen to have these parts on hand, but ordered them for me. I had them in just about a week.

Now the hard part. I found a microphone with no problem. That was the easiest of this group of parts to find. I had a microphone, but I needed a means to connect it. After many long hours of searching, I settled on a connector made by ITT. A five piece connector system costs $4.88.

After comparing the schematics for both the



The inside of the Tempo after modification.



The Tempo fmh after modification.

microphone and the HT, I discovered that the microphone switch alone would not handle the switching chores in the HT. Now here was a real problem. How does one get a manual slide switch to function from a remote hand-held microphone? I instantly thought of a relay operated switch. But most relays I had seen were way too big to fit into the limited space of the HT. Now I really had a problem, one that could kill this whole modification.

I dug into my parts catalogs and, after making a molehill out of a mountain, I found just what the doctor ordered. I found two Magnecraft relays that would work perfectly. Yes, I said two relays. Magnecraft manufactures all sizes of relays, and these two relays are the size of an integrated circuit, one DPDT and the other an SPST. These two parts were the second most expensive items after the microphone. They cost a total of $20.00 but are worth the cost for their size alone.

After waiting for four weeks for the relays and connectors, I could now go to the workbench. To start with, you need a small container to put the screws in. These are small screws and easy to lose. It is so hard to find a good screw – once you have one, you hate to lose it.

The first step involved the removal of all case parts. Then, taking the top plate and removing the useless meter, I inscribed the outline of the connector and filed the hole to fit. I found that I had to bend the tabs down on the connector in order for the connector to fit. To secure the connector, I liberally applied a plastic cement (commonly used to build plastic models). Setting this aside to dry, I then went to work on the circuit board.

For working on the circuit board you need to get out your surgeon's cap, gown, and mask as well as your trusty scalpel. The first step here was to locate both the B+ connections and the antenna switch-over. Once locating these, I was ready to start the operation. My assistant handed me the soldering iron, and we were off. I removed the meter connections first. Then, with the scalpel, I made an incision to sever the printed circuit between the points where the

antenna was switched (3 places) and the B+ switching (3 places).

Then turning the patient over, I inserted the DPDT relay on top of the existing slide switch with a little glue. I also adhered the SPST relay to the back of the unit's internal microphone. (Note: As the position indicators are hard to see once the relays have been glued down, it is recommended that a spot of white paint be placed on the underside for easy identification.)

The glue takes some hours to dry, so I left the patient under the anesthetic and went to the microphone. I soldered the wires to the connector and bent the tabs down, then put the plastic clip on. I was careful to write down which pin got which color wire. This done, I went to lunch. I returned after supper to finish, making the connection to the relays and the circuit boards. (Be sure that shielded wire is used in the antenna connections.)

Depending upon how you wish the unit to function, you may wire it so that it will work either with or without the external mike. However, I have rarely used mine without the external microphone. I find it to be much more convenient with the microphone. If you wish only operation with the external microphone, you may omit the SPST relay and simply disconnect the internal microphone.

Next I placed a Realistic microphone holder on the front of the unit by just peeling off the adhesive protector and pressing the holder into place. One thing about that Realistic microphone holder is that if you have a touchtone pad on the front of your unit, you can put the holder on a leather strap and slide it on your belt.

This group of modifications may be used on other HTs as well. ■

Mason MI 48854

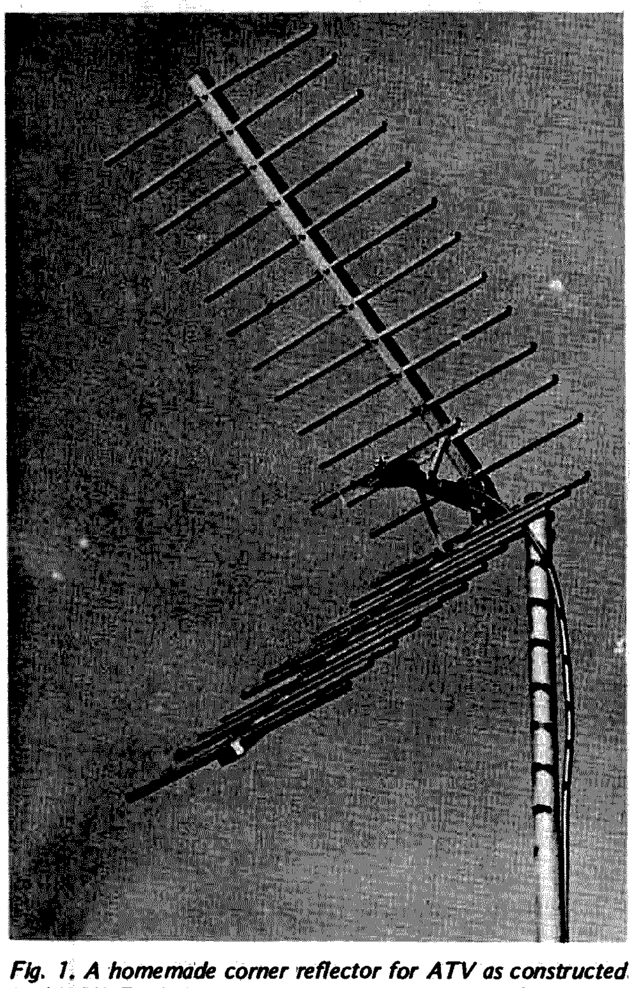

Fig. 1. A homemade corner reflector for ATV as constructed by WB8JXF. Maximum gain with such arrays is in the order of 10-12 dB, depending largely on the size of the reflector and its angle. This gain is easily realized, the antenna is simple to construct and match, and the array has a wide frontal lobe making aiming noncritical. These features make the corner reflector an ideal candidate for home construction where adequate facilities for precision antenna work are not available.

There is little doubt that ATV holds a fascination for many operators. If articles in the literature for the last few years are any indication, we well may be entering a modest growth phase for this fascinating mode. ATV, because of the incredibly wideband nature of the signals, is completely different from other modes with which amateurs are familiar, and even considerable experience in VHF and UHF is not sufficient to predict the requirements for a useful system. Quality results over a given path are not nearly so easy to achieve as some might suggest. Getting sufficiently good results to sustain local interest is a matter of being willing to invest a certain minimum amount of effort in setting up a quality system, and this is largely a matter of paying attention to innumerable details.

WB8JXF and myself have devoted a considerable period of time to developing the guidelines for an ATV system that would provide the kind of performance that would encourage others to give the mode a try. Some of the things we have discovered run counter to conventional wisdom, as expressed in many articles on the subject, but we have taken the trouble to document all aspects of system performance. If you follow some of our recommendations, you can expect to have the same level of system performance.

It is all too easy to quote results that can be obtained under particularly favorable conditions of location, terrain, or band conditions. Our approach has been extremely conservative, for it is the average performance level that must bear the brunt of day-to-day operations. You will occasionally be able to do considerably better when conditions permit, but our approach will be to pitch the system in terms of what you can expect in the way of performance whenever you turn the equipment on!

If you have been thinking about trying ATV, why not read on and see what you can accomplish? If you are giving serious consideration to ATV, and there is no present activity in your area, you should convert at least one other station. A working operation over a reasonable path is usually a prerequisite for interesting still other operators.

System requirements are largely related to the range involved in the specific path you wish to cover. Functionally, requirements break down into a few general range categories:

1. Less than 5 miles. In this category it is usually possible to achieve true "line of sight" conditions. If this is the case, it is possible to get by with low power or relatively simple converters or antennas.
2. 5-10 miles. About 10 Watts average power output is required in this category, assuming that quality antennas and converters are employed. If not, still higher power will be needed.
3. 10-20 miles. 10-100 Watts power output will be required for this distance, depending largely on the remaining system elements and the

terrain along the intended path.

4. 20+ miles. Regular work over extended paths will require good antennas and converters and a power output of 100 to 1000 Watts depending upon the path. Even the best of stations will have difficulty maintaining quality pictures out beyond 40 miles.

Note particularly that these categories are based on normal band conditions. Real DX of up to a hundred miles or more will be a rare event, usually coupled with excellent band conditions. The quality of such long haul pictures is such that they are acceptable primarily because they are DX. To sustain a local level of ATV activity requires consistent coverage over a much smaller area with pictures of consistently good quality. The purpose of this article will be to describe the requirements for the various system elements to achieve this end. Those elements include the antenna system, the receiving converter, the basic ATV exciter, high power options, and the matter of voice transmission along with the pictures. We will discuss each of these separately, but you should keep in mind that the results you achieve will depend on the quality achieved with each link in the system at both ends of the circuit. The pictures that are possible over a given path will be critically dependent on the weakest link in your system, and the gradual increase in coverage is largely a matter of optimizing each element of the total ATV system.

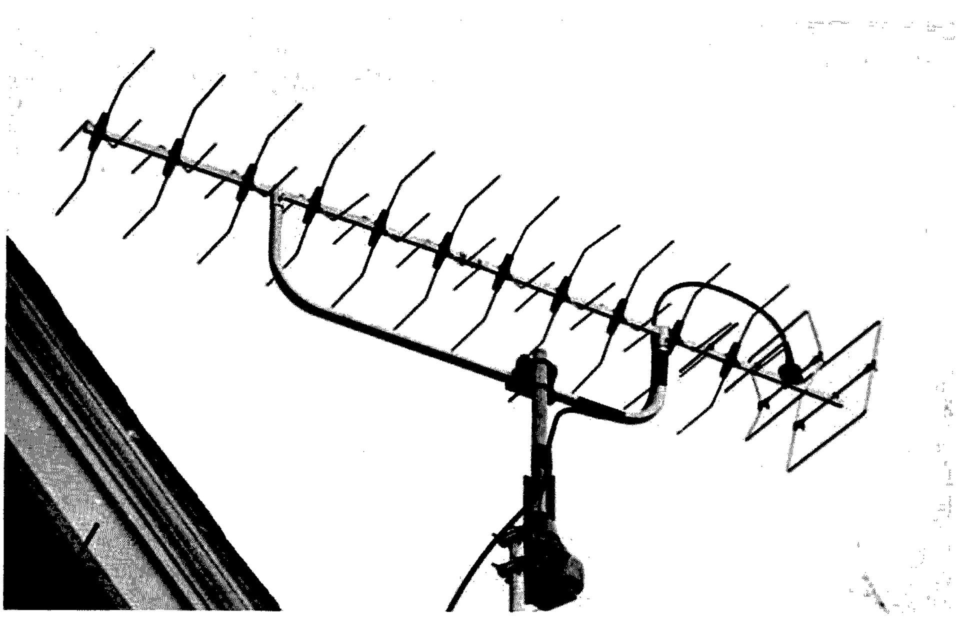

Fig. 2. The MBM48/70 antenna in use at the author's QTH. This antenna exhibits 17.3 dBi of gain and is essentially flat across the entire 420-450 MHz band. The driven element and reflector look somewhat like a combination of a quad and skeleton slot with two conventional directors transitioning into a series of cross-shaped elements each of which consists of four half-wave elements. Despite its unusual geometry, the antenna really performs as indicated by the specifications certified by the British Aerial Standards Commission and verified by our own tests. Like most high gain arrays, this one is extremely sharp in terms of pattern and is definitely not suitable for round tables, although it cannot be beaten for long haul point-to-point work.

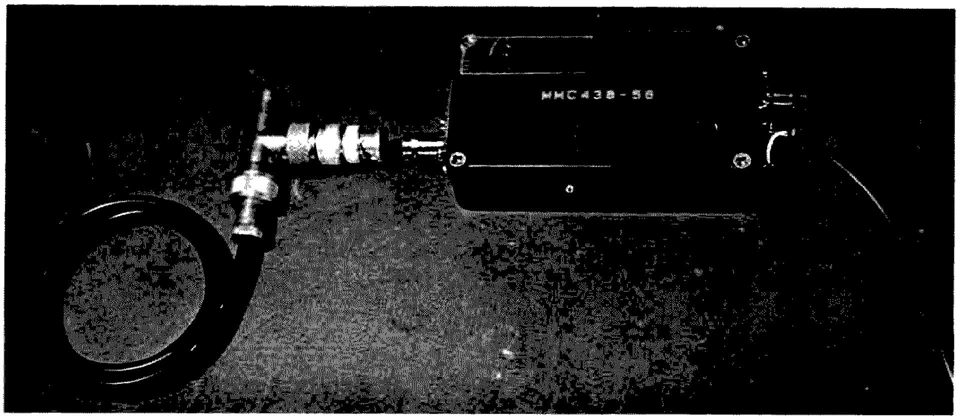

Fig. 3. One of the modified MMC 432/28 converters (MMC 438/56) used in our system. The photograph also shows the 1/4 wave stub for channel 6 which is used to remove a spurious mixer product between channel 6 and 23 in our area as described in the text. The use of such modern crystal controlled converters results in considerably better system performance than can be obtained with converted UHF TV tuners and outboard preamplifiers.

Antennas

The keys to success here are gain and bandwidth. Unless you just want to work down the block, you should not consider anything less than 10 dB, and you should try for all the gain you can get. Yagi arrays are out for ATV, primarily due to their limited bandwidth. Commercial antennas are cut for the wrong parts of the band and even a home brew antenna cut for your operating frequency will noticeably restrict the resolution of the pictures.

The simplest antenna that will do a reliable job is a corner reflector such as the one illustrated in Fig. 1. Such antennas are easy to construct,[1] are sufficiently broadband for TV use and are not critical to aim. About 10 dB gain is what can be expected. Several commercial antennas are designed to cover the entire 420-450 MHz band and thus can be used not only for TV, but for other modes as well. Table 1 summarizes some of these antennas. The KLM models are well thought of in ATV circles, although we have not used them. Our favorite is the MBM48/70 from J. Beam of Great Britain. This antenna is flat across the entire band yet packs a respectable 17 dB of gain into quite a compact package. This antenna, illustrated in Fig. 2 and marketed

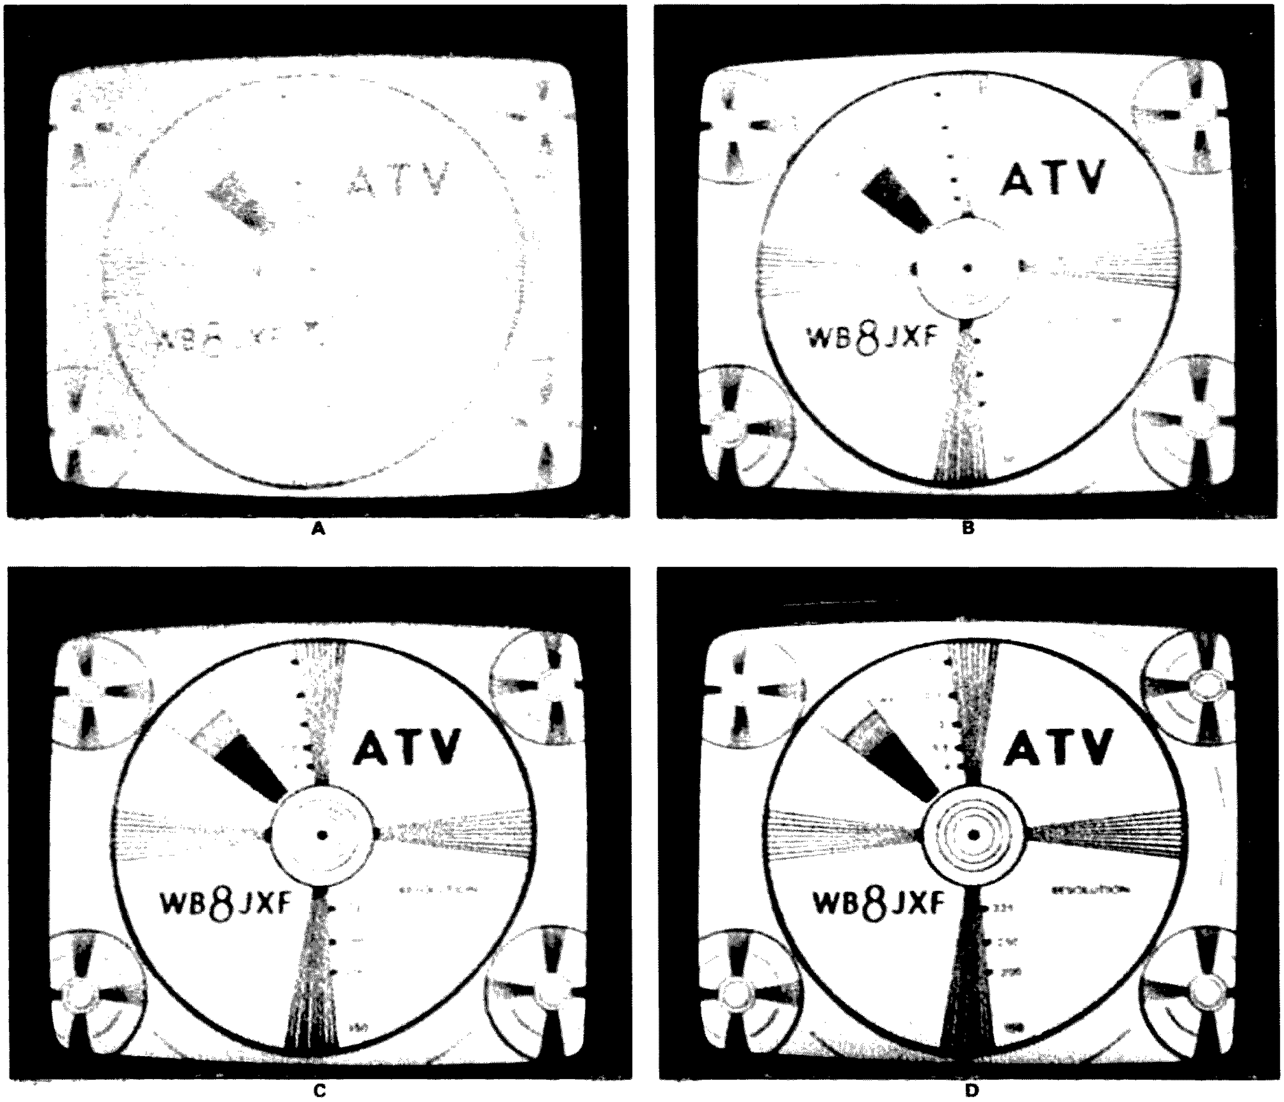

Fig. 4. Test transmission sequence from WB8JFX as received by the author using the MMC 438/56 converter. Antennas are those illustrated in Figs. 1 and 2, with 10 feet of antenna height at the transmitting end and 25 feet at the receiving end. The path is 8 miles over rolling low hills. Power levels are 10 Watts (A), 15 Watts (B), 20 Watts (C), and 30 Watts (D) average output. The important fact here is not the absolute power versus path length, for we have now reached the point where 5 Watts average power does as well over this path as 20-25 Watts in this test (by simply raising the antenna at WB8JXF's end). What is significant is the pronounced threshold effect for video signals. Even 1.5 dB additional system gain (B) will produce a surprisingly good picture; 3 dB is even better, as is 4.5 dB (D). Once you can see any video at all, a comparatively small increase in system gain at any point will give you a working operation. The other side of the coin is that if you are near the threshold, a similar small loss in system gain can ruin otherwise acceptable pictures! The proverbial "snow-free" pictures require at least 20 dB additional gain above the threshold, and you are not likely to get such pictures without line of sight conditions.

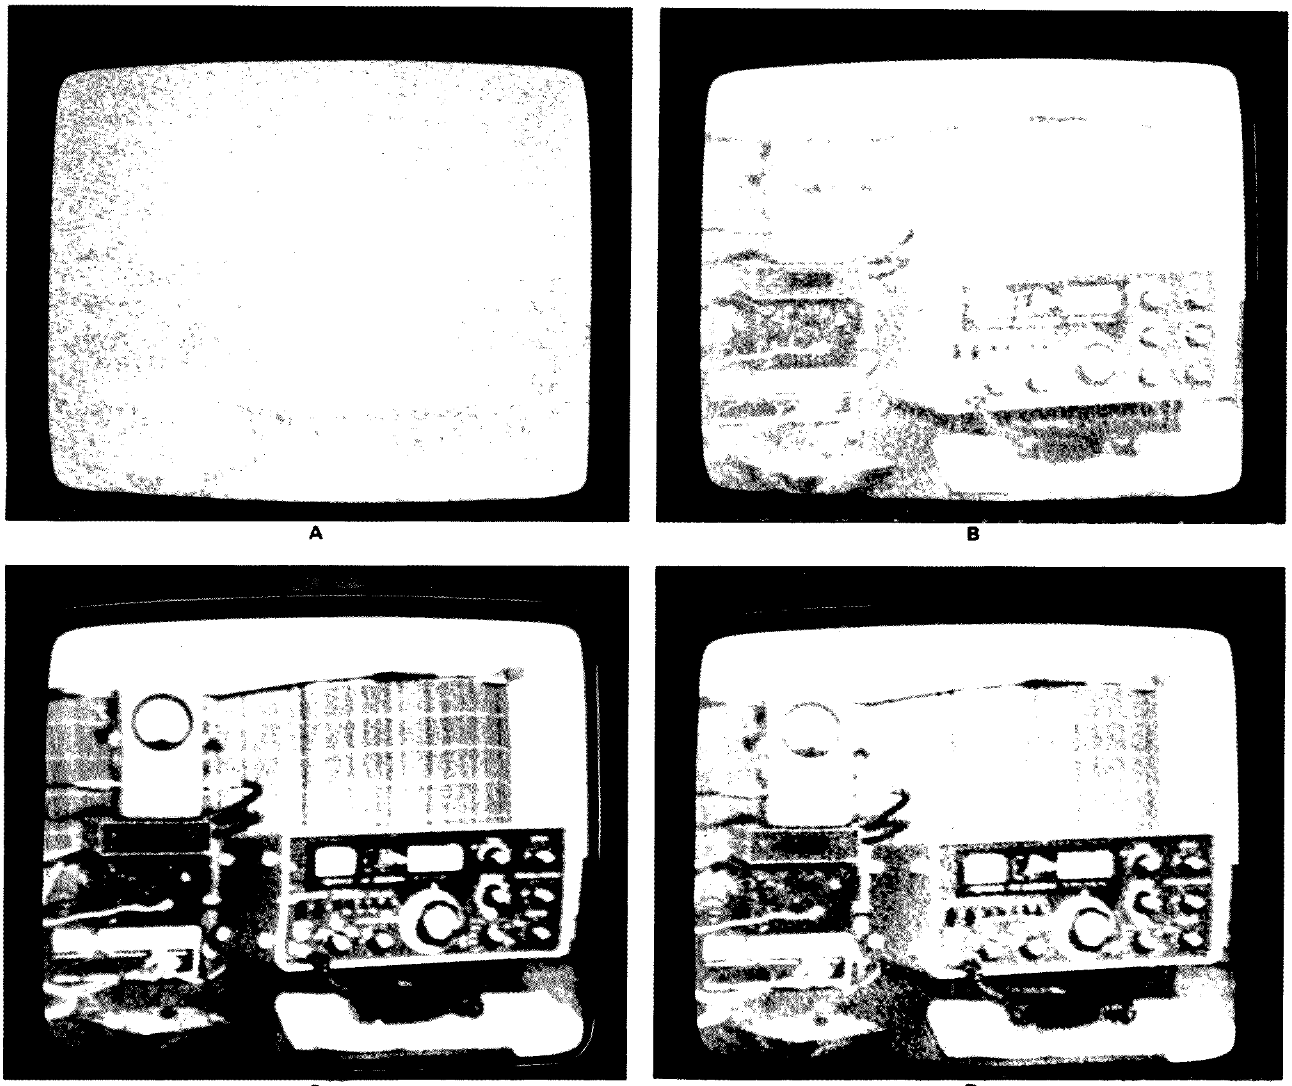
by Spectrum International, certainly has not received the attention that it merits based on performance.

Polarization is completely noncritical as long as it is matched at both ends of the circuit. You will probably be best off deciding between vertical or horizontal based on what other modes you might wish to play with on the band in addition to your TV activity. Height and location of the antenna are prime factors, however, and care should be excercised to insure minimum run of transmission line to the station. The antenna should certainly clear local obstructions, and height gain increases nicely up to about 50 feet. Above this the increase in height gain is usually counteracted by increased line losses, so super high antenna systems are really far from desirable.

There is considerable mystique about transmission lines for VHF and UHF work these days, and the feeling is that everyone should be using some form of hardline. Extensive measurements we have performed regarding direct line losses and system performance indicate that for runs of up to 50 feet there is little to be gained by going to the more expensive hardline. Use a good brand name RG-8 type foam cable, and you will do just fine. This does not mean you should use CB type cables. These have low braid density, and the braid is rarely tinned or plated — both factors leading to excessive line losses. Short runs around the shack can be handled with RG-58 foam



A B C D

Fig. 5. A test transmission sequence similar to that of Fig. 4, except that power levels of 5 Watts (A), 10 Watts (B), 15 Watts (C), and 20 Watts (D) are shown. Again, the pronounced threshold effect over a signal range of 3-6 dB above visibility is clearly evident.

with good results up to power levels of 50 Watts or so. Higher power levels will cause noticeable line heating with 58 foam and you will have to go to the larger cable sizes.

Equally misleading are some of the opinions circulating about connectors. Most serious UHF operators use type N connectors for larger cable sizes, dropping to BNCs for RG-58 cable due to the impedance bumps caused when the typical UHF series connectors (SO-239, PL-259) are used. Although such impedance bumps are real, they will not result in noticeable degradation in system performance if the venerable UHF connectors are installed properly. The newer solderless PL-259 connectors are ideal for use with RG-59 foam cables and are far less tedious to install than a BNC.

TR relays are a continuing problem. If you look at the astronomical cost of such relays these days, you would assume that they must perform. The sad fact is that the relays available to amateurs generally perform very poorly at this frequency and are a major source of lost power in transmitting and disappearing signals on receive. The only suitable route we have found is to

Model	Source	Gain	Length	Price
420-470-14	KLM	13.7 dBi	5 feet	$21.95
420-450-27	KLM	16.7 dBi	10 feet	$39.95
1:1 balun for above	KLM			$19.95
MBM48/70	Spectrum International	17.3 dBi	6.5 feet	$51.75

Table 1. Antennas suitable for use on ATV. Listed prices do not include postage. KLM Electronics is located at 17025 Laurel Road, Morgan Hill CA 95037. Spectrum International is located at Box 1084C, Concord MA 01742. The KLM antennas require the listed 1:1 balun, while the MBM48/70 can be fed directly with 50 Ohm cable. Stacked pairs or quad arrays may be employed for an additional 3 or 6 dB gain. KLM makes a variety of 2 and 4 port power dividers that vastly simplify the proper phasing and matching of larger arrays. A major advantage of these wideband antennas is that they are equally effective for other modes anywhere in the band.

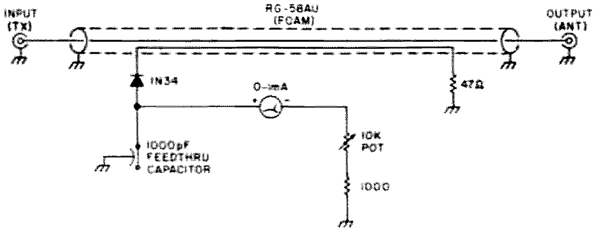


Fig. 6. In-line power output meter suitable for use on any VHF band. The coupling loop is a length of #24 enamel wire threaded under the shield of the braid of a length of RG-58 foam coax. Input and output connectors may be SO-239 bulkhead connectors but matching hoods (Amphenol 83-765) should be used to minimize the impedance anomalies at the connectors (see Fig. 7). Lead lengths for the terminating resistor (47 Ohms) and the 1N34 diode should be kept to a minimum. The diode is bypassed using a 1000 pF feedthrough capacitor. A button mica capacitor may be substituted but a conventional disc capacitor is unsuitable. The meter may be calibrated using a Bird or similar in-line wattmeter, with the 10k pot used to establish the desired full scale deflection.

shop the surplus outlets for military relays designed for use in the high UHF and low microwave region (like about 1 GHz). In any case, avoid 110 V relays, as these seem to have a tendency toward overheating coils and less than perfect performance.

Converters

A great deal of thought went into the subject of suitable converters. The conventional approach is to use a padded UHF tuner, usually with a quality preamp to compensate for the poor sensitivity of the tuner.[2] There are several objections to this approach. First of all, even the best of the outboard tuners employ passive diode mixers. This results in a mixer noise figure of 10-15 dB. A good preamp will have low noise and a gain of perhaps 20 dB. This gain is not sufficient to overcome the mixer losses and still set the system noise figure. The result is a higher system noise figure and a system loss of at least 10 dB compared to a system employing a low noise active mixer. The preamp does improve things considerably but you have not optimized either system gain or noise figure. The tunable feature of these converters was useful in the old days when self-excited transmitters might be operating anywhere in the band (or out of it on occasion), but is of marginal utility today when transmitters should be crystal controlled. The tunable converter is really only useful over a few megahertz if the preamp is peaked for maximum performance in any case. You can go to a broadbanded preamp but this will cost in terms of both gain and noise figure.

The answer, of course, is to go to a conventional crystal controlled converter of the same type that would be employed for work at 432. The converter we use is manufactured by Microwave Modules of Great Britain and is marketed in this country by Spectrum International and others. The basic MMC 432/28 converter is designed for 432 input and 28 MHz output and costs $65. For an additional $20, SI will peak the front end to your video frequency, install a crystal to bring you out on any low VHF channel (we use channel 2), and repeak the i-f output circuits. Thus for $85 you get a converter with a 6 MHz front end, a 3.5 dB noise figure and a total of 25 dB of conversion gain! This is cost competitive with the tuner-preamp approach if you tally up the cost of all the components of the latter system, and will outperform the latter in terms of both system gain and noise figure. Other converter manufacturers (Vanguard, Janel, etc.) will do similar jobs, or you can build any of the modern converters in the literature, making appropriate changes in the crystal frequency, LO, and i-f output circuits. The fine tuning control of the TV set will swing you several MHz, permitting the signal to be centered as desired in the i-f passband of the TV set.

My own modified MMC 432 converter is shown in Fig. 3. We adopted a video frequency of 437.25 MHz for a very practical reason. Most converter manufacturers offer 432 units with 50 MHz i-f output as an option. If 432 comes out at 50.00 MHz, then 437.25 will come out at 55.25 MHz, which just happens to be the video carrier frequency for channel 2! Thus a crystal for 6 meter output can be used, saving the long wait for a special crystal order. The only additional modifications to the converter involve a retuning of the i-f output coil for 55-60 MHz and repeaking the front end for the video frequency. Spectrum International labeled this version the MMC 438/56 and can deliver within a few days.

Fig. 3 also shows a fix for another kind of problem which you may encounter. In our area we have two powerful TV stations — one on channel 6 (video frequency of 83.25 MHz) and the other on channel 23 (video frequency of 525.25 MHz). Given our i-f, one of the many possible spurious mixer products falls right in our video window. Channel 6 is about 1 mile from WB8JXF's location, while channel 23 is less than 2 miles distant. He was faced with a very strong spurious signal while, even though I was about 9 miles from either station, I had a moderately strong image. After far too many evenings waiting for one or the other station to sign so we could get on with our tests, we decided to solve the problem. One solution would be a strip-line or coaxial filter in the input line to the converter, but I decided to try a simpler solution first. A coaxial T connector was mounted at the converter input with a quarter wavelength of coax (electrical length) cut for channel 6 on one arm, with the antenna lead on the other. This stub had no effect on reception at 437.25 but completely removed the spurious signal. WB8JXF tried the same trick, and it worked perfectly despite the very high signal levels at his location. In-line filters may be required for some types of interference due to front end overloading, but if one of the offending components is on a VHF frequency this simpler approach may work equally well.

Converted TV tuners do have one major use — they are so insensitive (without a preamp) that they let you monitor your picture when operating at moderately high power levels. Simply pad down the LO in the UHF tuner of your set, and you will have that capability. Direct monitoring with the high performance converter is not really feasible as it will overload with outputs over a few Watts.

Another factor worth mentioning is the TV set used as the i-f. It makes little sense to use a junker from the back room of the local service shops when modern sensitive sets are available for so little. If you get one with a power transformer (not a hot chassis), it can even be converted for use as a video monitor. I use a Sony TV-770 with excellent results ($139.95 at a discount store), but many other types are suitable and cost even less.

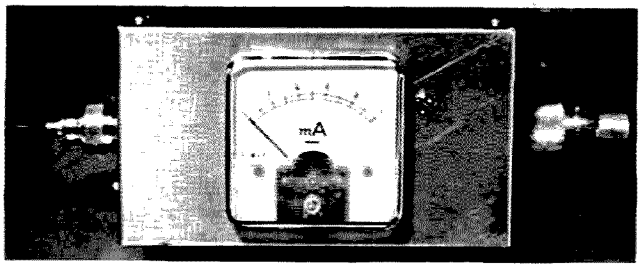
ATV Power Levels

Before discussing specific transmitter options we should have a realistic chat about power. The power requirements for ATV are directly

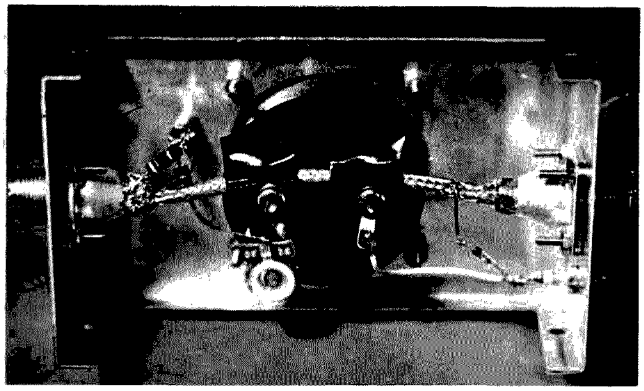
related to the path you intend to cover. The wideband nature of TV, coupled with the performance of rf amps and the agc threshold of the TV set, results in a very pronounced threshold effect over any given path. Over a distance of up to a few miles a low powered transmitter (@ 1 Watt) will yield acceptable results provided line of sight conditions exist. The latter condition is increasingly unlikely as the path is stretched out, and it is amazing how fast the video signal disappears despite the fact that QRP voice communication is possible over the same path.

Power output is a difficult question to address in the case of TV since there are several reference levels that can be used, including peak power, black level, and average power output level. Peak power is equivalent to the power output of a properly set up transmitter-modulator combination during sync pulse intervals. An in-line wattmeter such as a Bird will measure peak power only when the camera is switched out of the modulator input. Let us say that the transmitter will grind out 10 Watts under such conditions. Provided things are set up properly, if the camera is switched in but the lens is capped we should get an approximation of the black level output. This should be about 75% of peak output or 7.5 Watts. If we uncap the lens on an average scene we would get an average power output reading typical of what would be obtained under normal operations. This average level should run about 50% of peak output, or about 5 Watts. The average power percentage (relative to peak) will obviously vary considerably with the subject but it is a convenient reference, and, unless otherwise noted, all test results will be quoted as average power output.

Fig. 4 shows one path test between WB8JXF and myself at various average power output levels. Both of us are above average terrain and about 8 miles apart, with the intervening path consisting of gently rolling hills. Total system antenna gain is 27 dB (10 dB + 17 dB). Several intervening hills do not permit line of sight conditions at the antenna heights used in this and the following test. The first picture (10 Watts) is just at the threshold of visibility. Since the basic modulated exciter is running about 1 Watt output, additional system gain of 10 dB is required to reach the threshold of visibility. Note, however, that comparatively little additional gain is required to boost the picture from the threshold level to a point where it is quite acceptable. Referenced to the threshold, an additional 1.5 dB (15 Watts), 3 dB (20 Watts), and 4.5 dB (30 Watts) result in progressively better pictures. Depending upon your tolerance for snow, anywhere between 3 and 6 dB of additional gain will certainly produce acceptable pictures. Once you have boosted the signal to the point where it can be seen at the other end, comparatively little additional gain is needed to make the path usable. WB8JXF's antenna (a 10 dB corner reflector) was only 10 feet high for this test. Raising his antenna from 10 to 20 feet produces about 5 dB increase due to height gain, which means that pictures at the 10 Watt level would now be equivalent to those at 30 Watts with the previous antenna height. Note that all that is required is that the total system be increased by 3-6 dB, which can be achieved by any combination of factors at either end of the circuit. Conversely, a similar small drop in gain can have disastrous consequences if you are near the threshold in terms of system performance. Even over our short path it is easy to document small changes in path loss when operating at the 5-10 Watt average power output level.



A



B

Fig. 7. External (A) and internal (B) views of the in-line power meter shown in Fig. 6. The meter is kept in the transmitter line at all times to monitor power output.

The changes amount to no more than 3 dB fluctuations in path loss, but if you want acceptable performance every evening you must incorporate that 3 dB as a buffer in the form of additional system gain.

Fig. 5 shows a similar test sequence, only this time the threshold was at 5 Watts average with power increments of 10, 15, and 20 Watts shown for comparison. This series, showing some of the station equipment, also shows the Bird wattmeter used to monitor power output — you are not getting estimates based on guesses from a #47 lamp!

There is no doubt that the most effective means of monitoring power output in the 420-450 MHz band is a Bird wattmeter with a suitable set of slugs for the power levels you wish to use. It is highly doubtful that without the use of WB8JXF's Bird we would now be sending pictures back and forth. The problem is of course that the little devils are expensive and, although it is usually possible to borrow one for a short time to tune up a transmitter or check the antenna system, what is needed is an inexpensive yet reasonably accurate means of monitoring power output so that one needn't be afraid to tinker with the transmitter. The ever popular VHF Monomatch[1] works well for the lower VHF bands, but is more critical in layout to get a good null when used at 432. Numerous descriptions of more elegant directional couplers are available, but these are tedious to construct. It is possible to effectively modify the basic monomatch concept, however, if all we are interested in is measuring forward power. Such an approach is illustrated in schematic form in Fig. 6 and with photos in Fig. 7. This basic unit will effectively monitor power output up to about 100 Watts. If you run higher power, you can go to RG-8 foam cable and a shorter pickup loop. The internal pot can be set for full-scale deflection at any desired power level down to less than 1 Watt. Calibration is best accomplished using a Bird or

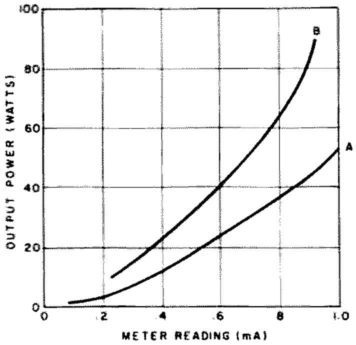


Fig. 8. Calibration curve for the author's in-line power meter. Curve A is for 432 MHz and curve B is for the two meter band. Provided the antenna system exhibits a low swr, once you have calibrated your meter you can reliably use it for power output measurements. The calibration curves will differ for each instrument, so there is no way to avoid the task of calibration if you want it to be useful.

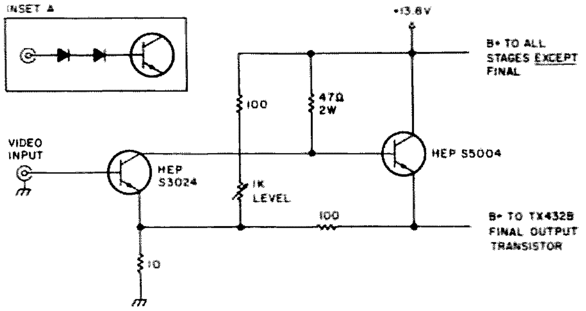

Fig. 9. Video modulator, designed by WB8JXF, for the TX-432B transmitter strip. Unless otherwise noted, fixed resistors are 1/2 Watt units. The 1k level control can be a 1/4 Watt PC pot mounted on the modulator board, or it can be a conventional panel mount control. Since it is usually not adjusted following setup, it is perhaps best to mount it internally to prevent tinkering. No heat sinks are required for use with the TX-432, but, if other transmitters are to be modulated (the modulator will sink up to 1/2 Amp), they may be required. Some tube-type cameras have a dc component in their output that will alter the bias on the input transistor. This can be eliminated by adding silicon diodes in series with the input (inset A) until the modulator provides proper video swing. 1N914 or other small signal diodes are fine here. No diodes will be required with solid state cameras. No terminating resistor is required at the input, as this function is taken care of by the input transistor itself. Several features contribute to the excellent performance of the modulator, including the use of high frequency transistors and the incorporation of dc coupling throughout.

similar unit for setup. A good 50 Ohm load is required, but this is easy at 432 – simply use 50-100 feet of RG-58/U (the older the better) terminated with a 50 Ohm resistor. Using the Bird as a reference, set the transmitter for the desired peak value (50 Watts for example) and then insert the meter into the line (starting with the pot at the maximum resistance setting). The pot is then advanced until full-scale meter deflection is obtained. Now reduce the transmitter power in steps (40, 30, 20 and 10 Watts for example), comparing the meter reading with the power as indicated by the Bird wattmeter. The meter may be used in several power ranges by switching in different pots with each range being calibrated as indicated. The adjustment pots should be internal to eliminate the urge to tinker with them and thus throw off your careful calibration at some later time. You can then use your meter readings to prepare a calibration curve. An example of such a curve is shown in Fig. 8. As long as you are working into a reasonable load (low swr) you will be able to estimate your power output quite nicely anywhere in the band. The meter can also be calibrated for other bands, but in that case you leave the pots as set for 432 and simply tabulate power output against the meter readings. The fixed geometry of the pickup loop causes the instrument to be less sensitive at lower frequencies, as shown by the two meter curve included in Fig. 8.

See how interesting it is to read all the articles in *73* each month! Even if you never intend to operate TV, you now have a reference for a simple and cheap instrument (less than $20) for keeping track of your power output in any mode on any VHF band.

Transmitters

There are many approaches that can be taken to arrive at a suitable transmitting system. One of the more common procedures is the modification of a commercial transmitter strip obtained on the surplus market. Some of these modulate quite easily with adequate bandwidth (RCA "Carfone" and G.E. "Prog Line"), while others are more difficult to use (Motorola T44). The primary advantage of this approach is that you have a well engineered transmitter operating at moderate power levels. The disadvantages are the bulky power supplies and the fact that replacement tubes are getting harder to find at reasonable prices. Both JXF and myself decided to opt for a more modern approach, starting with a basic crystal controlled solid state exciter. The one we use is the TX-432B from VHF Engineering (see ads in *73*). The kit for this strip costs $39.95, and one approach to using it as a TV transmitter is described in "Simple Amateur TV Transmitter."[3] The strip is constructed following the kit instructions, with the single modification involving re-orienting a single RFC so that B+ for the final can be brought out on a single land without using additional components. Attachment of the output coax to the board is critical for maximum output and stability. Short exposed leads are a must, and I achieved a 30% boost in output power by soldering the flange of a BNC connector directly to the foil groundplane with the center pin going directly to the rf output pin on the board. The object is to tune the exciter for maximum stable output into a 50 Ohm load. The final will take off on its own at certain tuning settings, and you should pull the crystal to check for this possibility when you think it is tuned up. You will get between 1 and 1.5 Watts output at 13.8 V, depending upon your specific output transistor. If you are getting much more output, you should suspect self-oscillation. The transmitter strip is quite clean when properly tuned. Heat sinks are provided for the driver and final output transistors, but, in both versions we have built, the pre-driver has run uncomfortably warm, requiring an additional heat sink.

Reference 3 describes a video modulator for the exciter, but another circuit, designed by WB8JXF, is shown in Fig. 9. This modulator is essentially noncritical in terms of parts placement and lead length to the transmitter board, and has more than adequate bandwidth for use of an aural subcarrier audio system (more on that later). With the camera connected to the modulator, the level pot should be adjusted for a

power output of approximately 50% of what you obtain with the camera disconnected. The camera should be set up on a properly lighted subject for this step. Final setting of the level control can be optimized while watching the picture. At one extreme the video will "white out" with very little power output from the strip, while at the other extreme you will have plenty of contrast but the picture will become unstable as you gradually eliminate the sync threshold. With normal video input the output will be 50% of peak, rising to about 75% if the lens is capped. Some older tube-type cameras have a dc component in the output signal, which will mess up the bias on the input transistor or the modulator. This problem can be eliminated by adding one or more silicon diodes in series with the input to the base until you have knocked the dc component down to the point where you get good video swing. An old Dage camera I used required three such diodes in series. No diodes will be required for solid state cameras. Fig. 10 shows a photograph of my own exciter and video modulator.

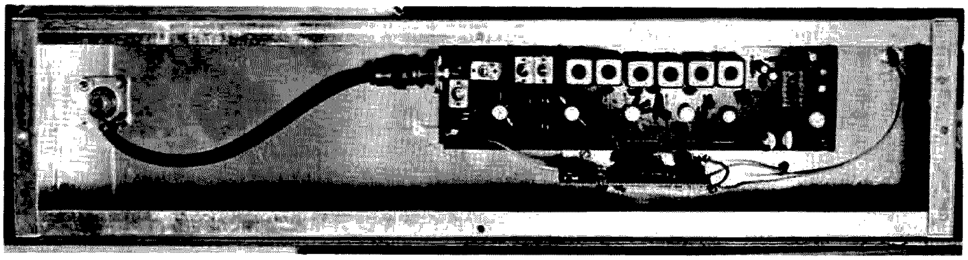

Fig. 10. The basic exciter and video modulator used in our ATV operations. In the author's version, shown here, the transmitter strip is mounted on standoffs with the modulator board mounted vertically next to the exciter strip. An extra large chassis was used, because I initially thought I would mount a power amplifier along with the exciter, but later decided to keep the exciter as an independent unit for demonstrations and portable work. A socket was used for the audio IC on the transmitter strip, but the IC is removed because the modulator is not being used at the present time. The additional heat sink added to one of the driver transistors (third from the left) shows clearly. A BNC connector is used to couple the rf off the board because this resulted in approximately 30% more power output than simply attaching the coax directly to the output pins.

When properly set up, the modulated exciter puts out a very nice picture that is limited in resolution only by the camera you employ. The main difficulty is that it simply does not have enough power to carry very far. I can shoot a nice picture around town (WB8JXF could do the same except that he doesn't live in a town!), but the picture quality drops off due to snow within a few miles. With everything optimized over the 8 mile path between us, we can exchange barely recognizable pictures with the basic exciter. The answer of course is higher power, and here WB8JXF and I took different routes, mostly to see what could be accomplished with various approaches.

The route I took involved the use of the Motorola MHW-710 power module as a linear amplifier. Reference 3 describes this as a "1 Watt in, 10 Watts out" module, but, as we shall see, this is not strictly correct. Two versions of the module are of interest to amateurs, depending upon your video frequency. The MHW-710-1 covers 400-440 MHz without tuning and the MHW-710-2 does the same over a 440-470 MHz frequency range. Both cost $41.50 and are available from Motorola distributors across the country. The module is basically an IC that requires very few additional components to do its job. Fig. 11 shows the schematic of my power amplifier using this module. A photo of the module and associated components is shown in Fig. 12. The module is one of the easiest-to-use rf components I have ever come across, and the amplifier is simplicity personified. The whole thing is constructed in a small aluminum chassis using a piece of double-sided glass board to provide for short ground returns. The board is mounted to the inner surface of the chassis with several screws and the input connector, to assure that the inner copper surface is actually at ground potential. A cutout in the board is provided so that the module can be mounted directly to the metal chassis, with thermal grease applied between the metal IC ground slab and the chassis surface. A large heat sink is mounted on the other side of the chassis, secured by the same screws that mount the IC. Use thermal grease at the interface between the heat sink and the chassis to assure good heat transfer. The amplifier is unconditionally stable if the exposed ends of the coax cables are kept very short — particularly the output line. Subminiature RG-174 is used to minimize lead stress on the module. Grounded IC pins, coax shields, and the grounded side of the bypass capacitors are soldered directly to the copper ground plane. A power supply capable of delivering at least 4 Amps at

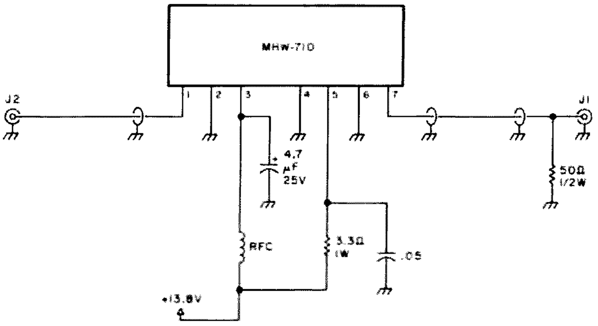

Fig. 11. Schematic for the circuit utilizing the Motorola MHW-710 power module in linear TV service. J1 is a Switchcraft 3501 FR phono jack. Interconnection to the module is made with a short lengths of RG-174 coax. A piece of double-sided circuit board with a cutout to accommodate the module (Fig. 12) permits short ground leads for input and output coax, bypass capacitors, and the grounded pins of the module. The schematic shows the IC pins as viewed from the top of the module. The metal slab of the module should be mounted directly to the aluminum chassis using thermal grease, with the heat sink mounted on the other side of the chassis in a similar manner. J2 is an SO-239 connector interconnected to the module with another short length of RG-174. Small coax is used to minimize lead stress on the module. Output lead length (exposed center conductor and shield at both ends of the output coax) should be kept to an absolute minimum. J1 is connected to the exciter by 50 feet of RG-174. This length is gradually trimmed until the proper drive level is obtained as outlined in the text. RFC — 8 turns #22 enamel on a 1 megohm 1 Watt resistor.

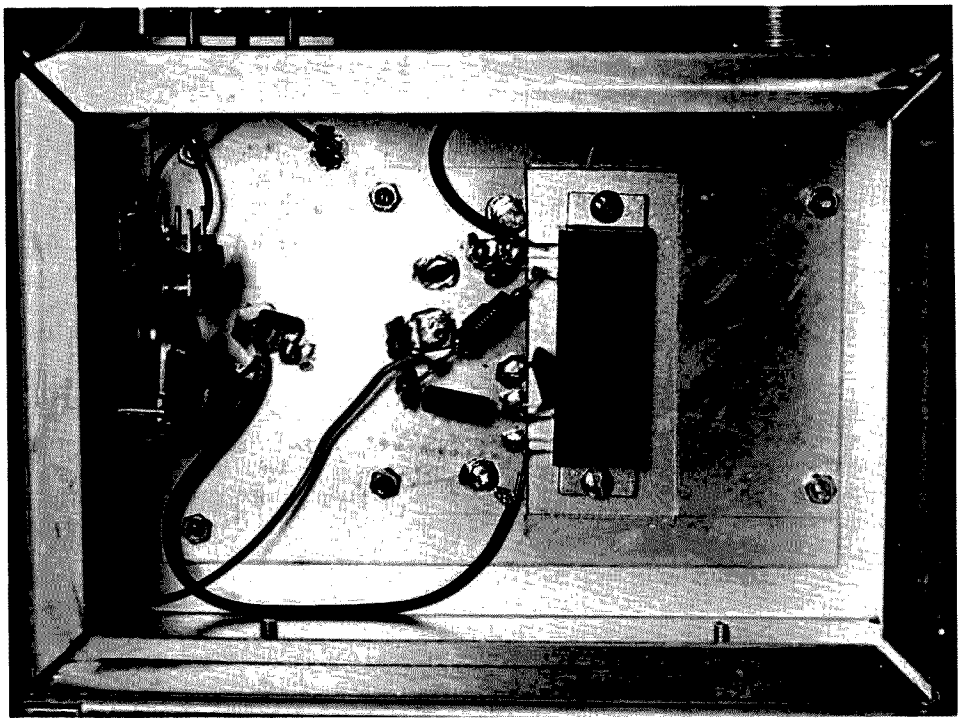

Fig. 12. Under-chassis view of the MHW-710 power amplifier circuit. A piece of double-sided glass PC board is mounted on the inside of the chassis surface to provide for direct ground returns for the power module pins, bypass capacitors, and the coax shields. This board is secured to the chassis with several screws and the input connector. A cutout in the board permits the metal mounting slab of the IC to be grounded directly to the aluminum chassis. Thermal grease is used to provide thermal coupling between the IC and the chassis. A large heat sink is mounted on the outside of the chassis, secured by the same screws used to mount the power module. Thermal grease should also be used in mounting the heat sink. Mounted in this fashion, the amplifier can run continuously at peak output (15 Watts) without overheating. The amplifier is unconditionally stable provided the free ends of the output coax are kept to an absolute minimum. The relay used to switch power to the amplifier during transmit is just visible to the left. Ideally the amplifier should work into a load with an swr of less than 2:1. I have made a few mistakes in this regard, and the module still works, but extended operation at full power into a large mismatch will probably do you in eventually.

13.8 V will be required, as the chip draws almost 40 Watts average input under modulation.

If driven directly by the modulated exciter, the module will put out almost 20 Watts, but very little modulation will be evident. Only 50 mW average drive is actually required, and the chip simply isn't linear when driven by 1 Watt from the exciter. The module performs excellently under modulation if we drop the drive level to the proper value, but we do not want to alter the tuning or voltage on the exciter, because this will alter its characteristics when modulated and will require that it be reset up if operated independently. Major changes in load will also have an adverse effect on picture quality. The answer turns out to be the use of a moderate length of RG-174 coax for coupling between the exciter and the module. This small coax is very lossy at this frequency and will drop the power to the module very smoothly while maintaining the proper 50 Ohm load on the exciter. Start with 50 feet of this cable (it's only \$.08 per foot). With no camera connected to the modulator, gradually prune the coax while watching the power output from the amplifier. Slow down when you get to 10 Watts and begin checking with the camera to be sure that black level and average output are tracking at 75% and 50% respectively. The module will not stay linear beyond 15 Watts peak, and I play it safe by stopping at 13 Watts. If you push for the last possible Watt, you will start infringing on the sync threshold, which will hurt your weak signal performance even if it is not noticeable in close. If you trim off a little too much coax, it's hard to put it back together, but you can recover by compensating with slight adjustment of the level control on the exciter. You should try to get it right using just the coax, however, for then you will have the exciter set up properly if you want to use it independently. Fig. 13 is a photograph of the complete transmitter, showing the coaxial coupling and the heat sink on the power amplifier. The result is a solid state ATV transmitter that performs as well as a converted surplus strip and which can be built for \$100-130, including packaging.

The basic ATV transmitter just described puts out enough power to function well over normal paths of 10-12 miles, and it can also be used to drive an amplifier in the 50-100 Watt class. There are several ways to go in getting to this latter power level. If you want to stay in the solid state business, there are a number of solid state linears which will do the job nicely. KLM makes two amplifiers that will do the job. Their PA10-35CL (\$139.95) will put out 35-40 Watts (average) when driven by the basic transmitter, and the PA10-70CL (\$245.95) will deliver about 70 Watts under the same conditions. VHF Engineering has recently announced the introduction of a similar series of amplifiers. Both companies, and others as well, are tooling up for amplifiers that will deliver comparable outputs when driven by the basic TX-432B exciter, but amplifiers with 35-70 or more Watts out with 1-2 Watts of drive are expensive. Costwise, it is far cheaper to incorporate the MHW-710 module to get enough drive to use one of the less expensive 10 Watt input amplifiers. All of these amplifiers require a regulated high current supply. (The PA10-35 draws 6 Amps and the PA10-70 requires 18 Amps.) So some pretty hefty power supplies are in order. Many manufacturers are marketing supplies for use with solid state HF transceivers in the 200 Watt range, but check the specs carefully if you plan to avoid the hassle of building a supply. Many of the HF supplies are rated for SSB service, and it is the continuous ratings that you should heed in making a selection.

Solid state linears with

their requirements for massive power supplies make it reasonable to consider tube-type amplifiers for more power output, as suitable supplies are readily available and often cost less than a low voltage supply required for comparable output with a solid state linear. WB8JXF went this route using the basic TX-432B exciter described earlier. One of the nicest amplifiers for outputs in the 30-100 Watt range is the cavity configuration using a 4CX250 described in the *The Radio Amateur's VHF Manual*.[4] This amplifier will deliver 30-40 Watts (average) on an 800 volt transceiver power supply and can push up to close to 100 Watts average at maximum rated voltage. Do not attempt to drive such an amplifier directly with the TX-432B exciter. WB8JXF did and lost the output transistor. It seems that the 250 tube series develops rather high rf grid voltages (a fact not mentioned enough in the literature), and the poor 2N5913 in the output of the exciter is only rated at 14 V on the collector! WB8JXF employs a 2C39 in grounded grid as a buffer between the exciter and the cavity, with excellent results. The 2C39 is set up to provide very little gain, and functions primarily to protect the exciter from the ravenous grid circuit of the cavity. Power output of the MHW-710 is more than adequate to drive such a cavity using lossy coupling, thus protecting the power module. If there is sufficient demand, WB8JXF could undoubtedly be persuaded to document his power train, which not only works well, but also employs some rather interesting ideas on coupling the exciter, 2C39, and cavity amplifier. If you want to go the limit on power, then the K2RIW kilowatt[5] is probably the best route.

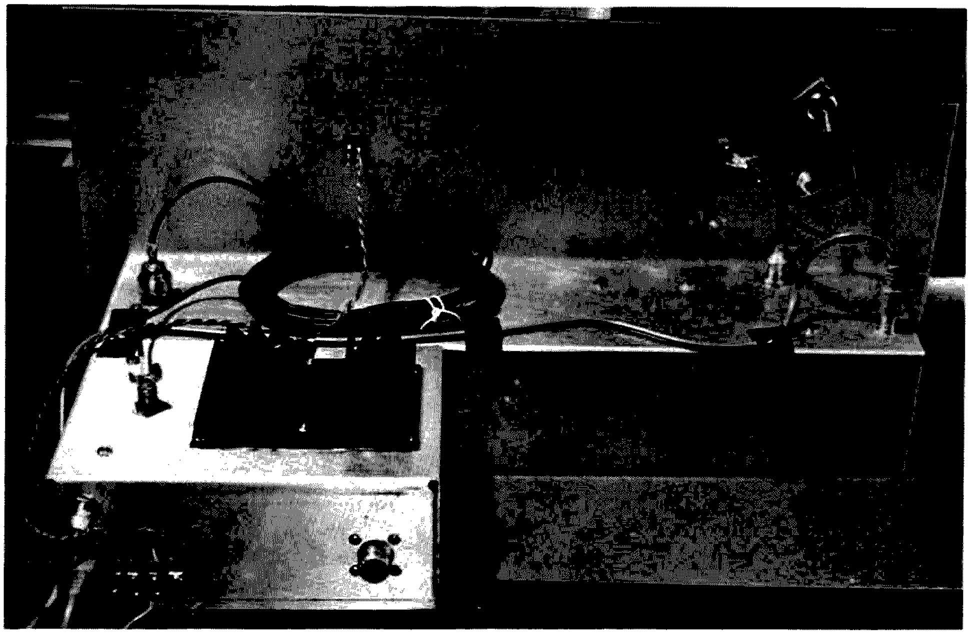

Fig. 13. Rear view of the complete basic ATV transmitter using the TX-432B exciter and video modulator (long chassis) and the MHW-710 power module (short chassis). The heat sink on the latter is visible, as is the coiled length of RG-174 used to drop the exciter power output to the proper drive level for the power amplifier. The front panel holds the TR switch, camera input and monitor output jacks, and video switch. The vacant space in the collection of boxes is for the cavity final (4CX250) which is presently under construction. An oversize panel is used to allow for metering and control hardware for this amplifier. 13.8 V comes into the power amplifier compartment and is jumpered over to the exciter. This permits power to be applied separately to the exciter if desired, with the latter connected directly to the antenna.

You will note that our system philosophy has involved the use of a well set up exciter with linear amplifiers to get to the desired power output level. You will occasionally read that such strings of linears result in a loss of picture resolution. This simply is not so if the stages are tuned properly. The linear approach does have the advantage that the power train can be broken down to any useful intermediate power level for demonstrations and such – something that is not possible with a modulated final. When we are talking about high powered tube finals, linears would appear to present a problem with power output, since maximum efficiency with AM linears is limited to about 35%. An interesting fact discovered in our tests is that excellent video quality can be obtained in class B. The finals can thus be biased AB1 for local work and easily shifted to class B for really long haul schedules. The only effect of the latter operating conditions is a very slight compression of the grey scale, which actually may improve subjective picture quality under conditions of high noise. The effect is hardly noticeable locally, but you can always shift back to AB1 for color or other critical applications. Given the flexibility of linear power trains, this approach seems to us to be better than grid modulation of the final, for there is little or no difference in effective power output at any given input when the power difference could actually make or break a contact. For those who might doubt, the test photographs of Figs. 4 and 5 were made with the cavity final operating in class B!

Sound

There are many ways to handle the matter of sound to go along with the pictures. The easiest way is, in our opinion, the best. It involves using your existing phone equipment on another VHF band (2 meters is ideal). This gives you a reliable audio link that is so essential in setting up a system and permits voice communication without firing up the video gear. Another substantial advantage of this approach is that your audio commentary will receive maximum exposure and perhaps get you some new converts. If you put the voice up with the video signal, no one but your cronies will hear and you cut your chances of snagging new converts.

Another approach is to simultaneously FM modulate the exciter, recovering the audio on a separate FM receiver tuned to the carrier frequency. This is easy with the TX432B exciter since there is an FM modulator already on the board, but it is hard to keep sync buzz out of the receiver, particularly in the case of a signal that does not limit fully during video modulation.

Audio in conjunction with the TV receiver can be

accomplished in two ways. The first is the use of an aural subcarrier unit in which a voice modulated 4.5 MHz oscillator (FM) is mixed with the video at the input to the modulator of the TV transmitter. This results in two FM sidebands 4.5 MHz from the video signal. The upper one is demodulated as sound in the TV set. Several problems are associated with this method. First, the video amp must be flat to 4.5 MHz (the one in Fig. 5 is) to pass the FM subcarrier. The more power you apply in the subcarrier, the more you take from the picture signal, so compromise is required. The subcarrier unit must be designed so that it does not load the modulator input if a loss of resolution is to be avoided. A nice subcarrier circuit is described in "Practical Ideas for the ATV Enthusiast."[6] The most elegant approach is to use another FM transmitter 4.5 MHz above your video carrier frequency. The most effective sound level is achieved with an output level from the voice transmitter of 1/3 to 1/2 of the average video output. This ratio is in terms of the effective radiated power, so the antenna gain for the voice transmitter should be taken into consideration. Simple yagi arrays are fine here since the voice signal is narrowband.

Summary

This article has covered a lot of ground in attempting to document an effective ATV system. The system outlines provided are realistic, and if you are interested in trying ATV you can implement them with expectations of success. If you are within line of sight of an ATV repeater, you can undoubtedly get by with far less in the way of equipment, but our approach has been oriented toward point to point service. When band conditions are good, you will get even exceptional results with a given power level, but you will have assembled the station with a realistic idea of what you can accomplish at any time.

I first got into ATV when virtually every item of equipment had to be built from scratch, and when you were done the technology was such that you occasionally wondered if it was worth the effort. Today the effort and costs are actually less than they used to be, and there is no comparison in terms of the results you can achieve.

ATV is a fascinating aspect of our hobby. You will have to tinker to optimize the system, but there is lots of room for real experimentation. The biggest stumbling block is simply getting an effective two-way operation going. I think we have developed some workable guidelines to make that task easier.

Once you are on you can branch out in any direction – color, Pong, microprocessors via ATV time-sharing – you name it. The name of the game is both fun and a little education. If you do give it a try, you will not only enjoy demonstrating your efforts, but will also have accomplished something far more in the traditions of amateur radio then simply playing with store-bought goodies. For about what it would cost for a fancy FM toy, you can come up and join the video freaks for some real pioneering – why not give it your best shot?! ■

NEVER SAY DIE

EDITORIAL BY WAYNE GREEN

from page 95

delegates found little enthusiasm for this move with the other countries, and head counts of the countries indicated that we were very far short of the needed majority.

On the opening day of the conference, the U.S. managed to get the Netherlands to start things off by proposing the 3-30 MHz postponement, sort of in the hopes that it wouldn't look as if the U.S. was pushing for it, and thus when it was defeated, it would not be a U.S. defeat. The entire assembly of the plenipotentiary meeting was thunderstruck when the Soviet Union rose and seconded the Netherlands motion. With a large number of small nations in the U.S.S.R. pocket, the motion was carried and amateur radio was saved until the next conference.

How did this happen? It was a pure fluke. Khrushchev had just visited the U.S. and been most cordially welcomed by Ike. When he returned home, he wanted to make sure that his good feelings toward the U.S. were reflected, and it happened that the first opportunity to show friendship between the U.S.S.R. and the U.S. came at this ITU meeting in Geneva. When you consider that not long after this Gary Powers was shot down and the U.S.S.R. mood changed, you can appreciate how we lucked out.

1964 – THE ITU

As more and more of the emerging nations joined the ITU, the balance of power changed from the U.S./ European block to the third world. The American Secretary General of the ITU was voted out and replaced by an Ethiopian. The American who really ran the ITU was fired and the whole place changed to reflect the new African/Asian influence.

After the Ethiopian Secretary General, they voted in one from India, with the second man in command from Australia. Remember, if you will, the 20 kHz ham band proposal of India and the 50 kHz proposal of Australia. Amateur radio no longer had good friends in high places.

1966 – I TRAVEL

With a possible frequency conference scheduled for 1969, it seemed like time to take stock. I decided to take a trip around the world and visit some of the countries that would be deciding the future of the ham bands at the ITU. My trip took me to Kenya, Uganda, Tanzania, Ethiopia, Sudan, Egypt, Lebanon, Syria, Iraq, Iran, Afghanistan, India, Nepal, Burma, Thailand, Singapore, Australia, New Zealand, New Caledonia, Fiji Islands, Western Samoa, American Samoa, Tahiti, and back to the U.S. I DXpeditioned from 15 of the countries, working tens of thousands of amateurs as I traveled.

In each country, I got together with the national amateur radio society of that country or with the local amateurs where there was no significant society. In several, I visited the ministers of communications to explain the importance of amateur radio to them and their countries.

One of the results of this trip was the development of the concept of having ham ambassadors visit smaller countries to point out the benefits to them of encouraging amateur radio. This was written up in my November, 1966, editorial in *73 Magazine* . . . written while I was in Sydney, Australia.

While in Ethiopia, I got together with the ex-Secretary General of the ITU and explained amateur radio to him. He had very little background in it and became most enthusiastic when I pointed out the benefits to emerging nations of the hobby. I showed him how people could be encouraged to learn electronics and communications on their own time and pretty much at their own expense, and thus become a very valuable resource for the country . . . technicians and engineers. He suggested that I should get together with the current Secretary General of the ITU when I was in India, and he helped arrange a meeting.

In Delhi, I did meet with the Secretary General and discussed the importance of amateur radio to emerging nations with him. I pointed out that small country students normally think in terms of being lawyers, doctors, or civil servants, and the concept of an engineering career is lost. With amateur radio as an impetus, many of the students would want to try for technical school training and the country would benefit greatly.

Communications is the basis for growth of any civilization, and when a country has to import everything electrical and electronic, including technicians at $200 a day from Sweden or Switzerland, they are able to buy very little in the way of telephone systems and radio communications. With local technicians, they would be able to buy much more.

The Secretary General was enthusiastic when I suggested that I could provide a sample set of amateur radio regulations for the ITU to make available and recommend to smaller

Simple Electronic Siren

-- it's loud!

Ray Megirian K4DHC
606 SE 6th Avenue
Deerfield Beach FL 33441

"Whatcha makin' Dad?"

"A microcomputer, son."

"What's it do?"

"Well, when it is finished, I hope to program it so it will run my rig. Every fifteen minutes it will initiate a receiver scan of all the ham bands to search for rare DX. If a rare callsign is recognized, it will tune up the transmitter, select the best antenna, call the station, and sound an alarm so I can take over. It will also make out a QSL card and record the contact for my log."

"Oh."

"Why don't you go next door and play with Buddy so I can get this thing finished. It's costing me a bunch and I don't want to make any mistakes in the wiring."

"Yeah, ok. His dad just made Buddy a turn signal for his bike. He makes a lot of neat things for Buddy. He's real smart. See you later, Pop."

Then it hits you. Is it really that long since you were pouring sand into a length of copper tubing so you could bend it into a tank coil for that super new 5 meter modulated oscillator? And it can't possibly be so many years since you thrilled to the sound of Big Ben on 49 meters with a one-lunger on a cigar box chassis. Transistors? Who needed 'em! Your vacuum tube superregen ran on 6 volts with the grids reversed. Remember? Ah, those were the fun years.

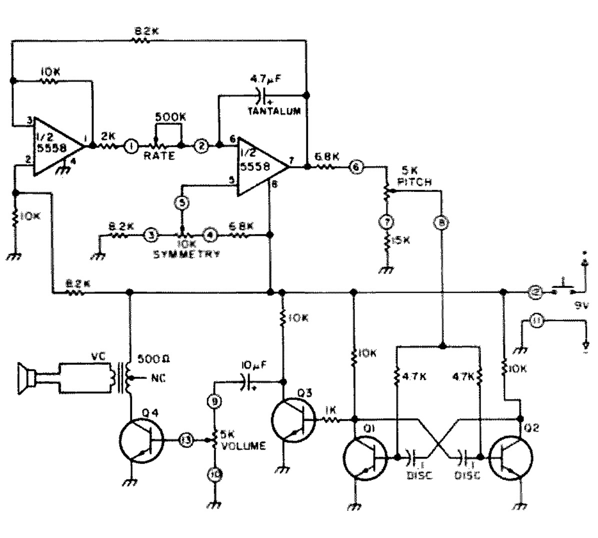

Fig. 1. Schematic for the electronic siren. The circled numbers correspond to numbered pads on the printed circuit board.

An Electronic Siren

Well, here is a fun thing you can build in a couple of hours that is guaranteed to make you a hero in the eyes of any youngster and just possibly the envy of your neighbors. What I'm selling is an electronic siren. Not a new idea by any means, but this one has enough operating controls to make it particularly appealing. The circuit is self-starting, simple, and runs on standard 9 volt radio batteries. Drain is low enough so you won't have to make a trip to the drug store every day for fresh batteries. You can vary the repetition rate from a long wail to a rapid warble, control the volume from soft to annoying, vary the pitch and the symmetry.

The circuit, as shown in Fig. 1, makes use of a type 5558 dual op amp and 4 NPN transistors as the active elements. The IC is used to generate a triangle wave much as any basic function generator. This triangle can be distorted by means of the symmetry control to form either a fast rise or a slow rise sawtooth. This signal is applied as base bias to the astable multivibrator formed by Q1 and Q2. As the level of the triangle or sawtooth rises and falls, the charging time for the cross-coupling capacitors varies and causes a change in multivibrator frequency. Output is taken from one side of the multivibrator and squared up by direct-coupled amplifier Q3. The audio output stage, Q4, is pulsed on and off by the square waves and provides plenty of noise with little expenditure of battery power.

The siren contains about 5 dollars worth of parts. Depending on the cost for an enclosure, the total outlay shouldn't exceed 10 bucks. All resistors are ¼ Watt. The output transformer isn't critical. I used a 500 Ohm to voice coil type with PC leads for use with the board layout shown in Fig. 2. The tran-

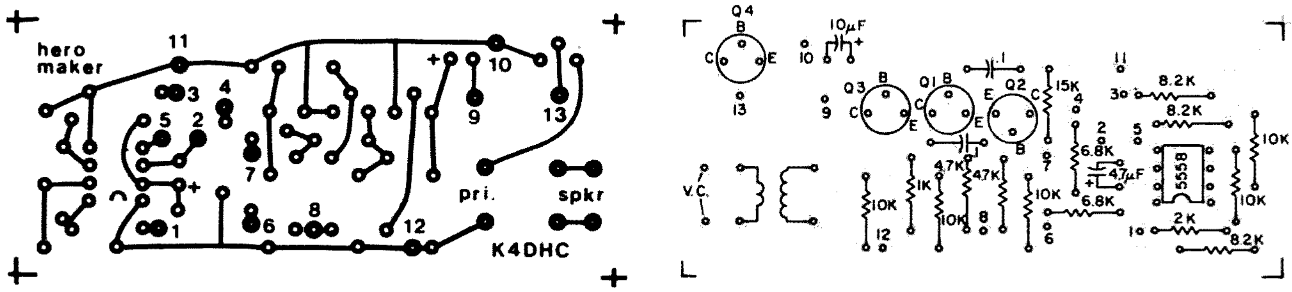

Fig. 2. PC pattern and parts placement for the Hero Maker.

sistors are NPN silicon units. Mine were house-numbered cheapies in TO-18 cans which I picked up years ago. The .1 uF capacitors are 50 volt discs. The 10 uF coupling capacitor in the audio section is an electrolytic. The 4.7 uF capacitor used in the integrator section of the triangle generator should be a tantalum unit for best results. I used a small dipped tantalum which fits the board layout. An axial lead type may be used by mounting it hairpin fashion. The operating switch can be either a push-button or a toggle switch to allow hands-off operation when used on a bicycle.

Operation of the controls and their effect on the siren sounds will become apparent after a few minutes of use. The symmetry control is the only one whose purpose may elude you at first. The complete cycle consists of an audio tone which starts at a low frequency and rises to a high point before retracing its way back to the starting frequency. If the symmetry control is set at one end of its range, the rising wail of the siren can be stretched out to occupy the greatest portion of the cycle time or the falling wail can be made longer with the control at the other extreme. Somewhere in between, a symmetrical triangle is generated and the rise and fall portions of the siren sound will be equally long. The pitch control varies the actual range of frequencies covered in one complete cycle and the rate pot controls the number of complete cycles per unit of time.

Most of the common siren sounds can be imitated with this toy and it will furnish hours of amusement for the youngsters, provided your nerves hold out. If the kids do mount these on bicycles, it might be worth a little extra effort to make them removable. One of our neighbors' boys had his bicycle ripped off less than 12 hours after installing one of these sirens. It makes the prize just that much more enticing to a thief.

So there it is; your golden opportunity to be a hero. Why not put digital readouts, microprocessors, RAMs and ROMs out of your mind for a couple of hours while you build something just for the fun of it. Have a ball! ■

EDITORIAL BY WAYNE GREEN

from page 174

countries.

Upon returning from the three month trip around the world, I found the magazine in dire straits . . . a month behind in production and almost bankrupt. I had to get things in hand and work hard for several months before I could get to the substantial job of writing a set of international amateur radio regulations. I was partly done with them when I read in the newspapers that the Secretary General had suddenly died. Well, so much for that project.

1969 – ITU

I visited the ITU in Geneva at every opportunity to keep in touch with what was going on under the surface. While the African/Asian countries were strong enough to influence the vote of the ITU on many matters, they were not well enough organized to force a general meeting to change the shortwave frequency allocations. The European nations were so far able to block every attempt at frequency talks.

1971 – ITU

With the African nations growing stronger, a satellite frequency conference was called for 1971 and the U.S. participated, with the ARRL representing amateurs worldwide. The ARRL went into the conference with 237,254.77 MHz of satellite frequencies allocated to amateur radio. They came out with 7.5 MHz . . . and only 3 MHz of that above 150 MHz! Thus they managed to lose 237,247.27 MHz of the amateur satellite allocation.

This loss was duly reported in *QST*, with the explanation that the conference might have gone better if they had done their homework. If they had done as I suggested in my November, 1966, editorial, and sent ham representatives to visit the foreign countries to make them aware of the benefits of amateur radio to them, we might have thousands of megahertz of satellite frequencies today. They found many of the ITU delegates did not understand amateur radio and few had any knowledge of how it might benefit them.

Satellites were still pretty new in 1971, so the impact of the loss was not generally recognized. Now, as we think in terms of satellite communications as a way for amateurs of all countries of the world to get together via synchronous satellites, we are beginning to appreciate what has been lost . . . and lost forever.

1979 – ITU

The next conference is scheduled for 1979, and there is no indication that it will be anything but a replay of the 1959 situation, only without the U.S.S.R. to pull our fat out of the fire. There will be even more pressure for eliminating the shortwave ham bands, and fewer friends to try to hold them for us.

The ARRL has been generating a smoke screen of proposals for new shortwave ham bands, none of which has been seriously accepted by even the U.S. delegation.

Do we yet have ham ambassadors visiting the third world countries to sell them on the value of amateur radio to their countries? You know the answer to that . . . no.

1970 – JORDAN

While visiting Jordan and operating JY1 from the Royal Palace, I talked with His Majesty King Hussein about my plan for encouraging amateur radio in emerging nations as a way to get technically enthusiastic students who would then opt for engineering careers. Hussein asked me to explain the plan to his government, which I did . . . and it was put into action, despite a fierce civil war between Jordan and the resident Palestinians which began only a few days after I left.

I returned again to Jordan in 1973 and found that there were active ham clubs in every major city in Jordan, with over 500 licensed amateurs. The rules and regulations were essentially those I had prepared for them and sent over shortly after my return to the U.S. in 1970. As a result of the large number of technically interested youths in Jordan, the government was thinking in terms of setting up a radio crystal manufacturing plant and a small plant for making VHF transceivers. These would have been totally impossible projects just three years before.

In Jordan, the King supplied ham stations to each of the youth clubs and sent one man around to conduct code and theory classes. It worked.

The growth of amateur radio before the ARRL pushed through their "incentive licensing" plans was 11% per year. If the League had not insisted on trying to force amateurs to get higher class licenses by taking frequencies away from them if they did not, we might have seen amateur growth continuing at that level, and we might have about 1,250,000 amateurs today. With numbers like that, we would not be having to worry about losing 220 MHz and other UHF bands.

Digital To Audio Decoder

-- for the blind operator

About a year ago, I had an accident involving an exploding car battery whose shrapnel left me blind in one eye. As the anniversary of this unfortunate event passed me by, I got to thinking about how lucky I am to be blessed with sight and about those hams not so blessed. I thought how difficult it would be to do something most of us take for granted, like reading a frequency counter or a digital voltmeter.

So here is a device which overcomes one of the many difficulties experienced by a blind person involved in any phase of electronics. In essence, it converts a binary coded decimal input, from any suitable piece of digital test gear, into a sequence of different tones — ten tones representing the numbers zero to nine, and the length of the sequence equal to the number of digits displayed, plus a sign indicator, if desired.

Photo 1. Digital to audio decoder and Heathkit IB1100 frequency counter.

Theory

Some readers unfamiliar with logic design may have a little trouble wading through the audio decoder's workings, while others of you have probably spent the last ten minutes exploring the schematic and now understand its working better than I do.

Perhaps the best place to start is with the sequence generator consisting of IC5, IC6, and IC7. IC5 is a familiar 555 timer connected for astable operation, which means that it generates sharp edged pulses, about twice a second as determined by time constant R10-C1. IC6, a decade counter, advances one count as the 555's output swings low. When the counter counts to nine, the next pulse resets its count to zero.

The count output, at terminals 1A, 2B, 4C, and 8D, is fed into IC7, which converts the 7490's BCD output to a one out of ten output. To clarify this a bit, suppose the 7490's outputs were 1A=0, 2B=1, 4C=1, 8D=0. This is the same as one 2 plus one 4, which is 6. Now only one of the 7442's ten outputs is activated. Output six drops to zero. When another pulse arrives from the 555, the 7490 will now store a "seven" and the 7442's output seven will be a zero. The rest (including six) will be a one. So only one output is low at a time, and every tenth pulse starts the sequence over.

The sequencer drives the digit scanners IC1-IC3, aided by inverters in IC8. (An inverter changes a zero to a one and vice versa.) The idea is to look at one digit at a time and convert its number into a corresponding tone and then move on to the next digit and repeat the process. But I'm getting a little ahead of the story here; first the right digit has to be selected. The NAND gates in IC1, IC2, and IC3 are of the open collector variety. They provide one of two output states, much as a conventional NAND, but, instead of ones and zeroes, these put out high impedances instead of ones and zeroes as in the regular NANDs. *Caution:* These are 7401s or 7403s but *not* 7400s. The inputs to these open collector gates allow us to: 1) pass data from the data input terminals to the output terminals; and 2) make the gate outputs look like they are open switches. As long as we apply a data pass signal to only one of several gates whose outputs are tied together, the others look like they aren't there! The job of the sequencer, then, is to apply a "one" pass command to only those four gates that are the input path for the digit we want. Since the data is inverted by the digit scanners, IC4 reinverts the data to its proper form. Four gates must be used at a time, because it takes four bits to represent a number from zero to nine.

At this point, the four outputs of IC4 first mimic the 100s place of the connected digital test equipment,

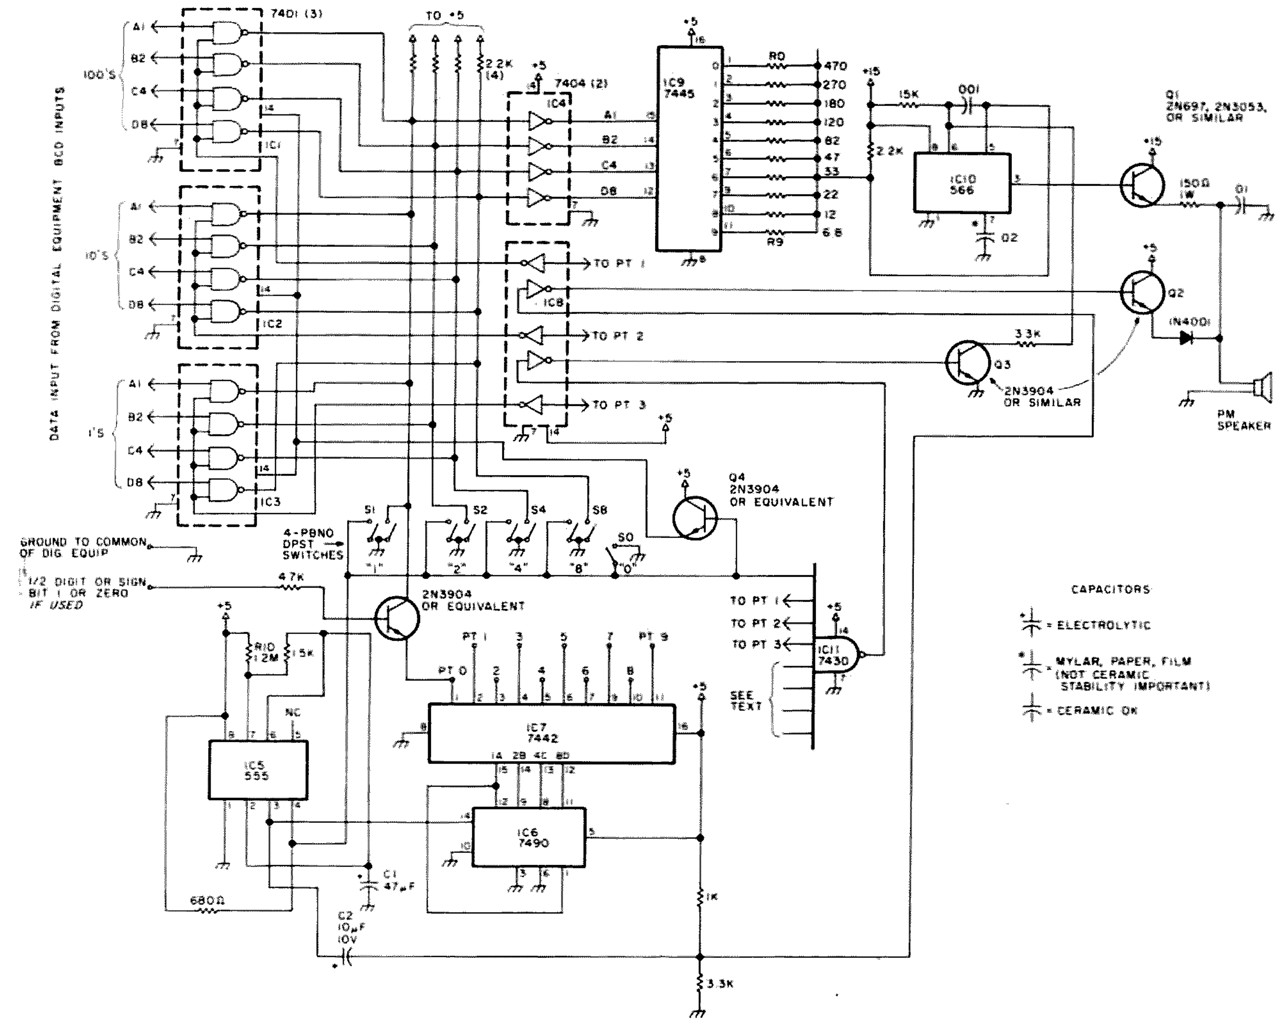

Fig. 1. Schematic of 3½-digit digital to audio decoder. Resistors should all be ¼ W ±10% or better, unless noted. If not specified, values are given in kΩ, i.e., 470 = 470k.

then the 10s place, and finally the 1s place, as the sequencer steps from 1 to 2 to 3. You may wonder what sequencer position zero does. It is the sign bit, in case you wish to connect the audio decoder to a digital VOM with this feature, or use it to indicate overrange on a counter as I did.

IC4's output feeds IC9, which is another BCD, to one out of ten decoders, as we talked about in the sequencer. It has one important difference though: Its outputs are open collector, just like the digit scanner gates. So once again, only the corresponding output of IC9 will be brought low for any given input number. This switches a different resistor into the voltage controlled oscillator circuit, IC10, which in turn causes it to see a different voltage and generate a different tone. I set up the resistors to provide an increasing tone for increasing numbers. The resistors could be selected to play musical notes. Q1 merely amplifies the tone to drive a speaker.

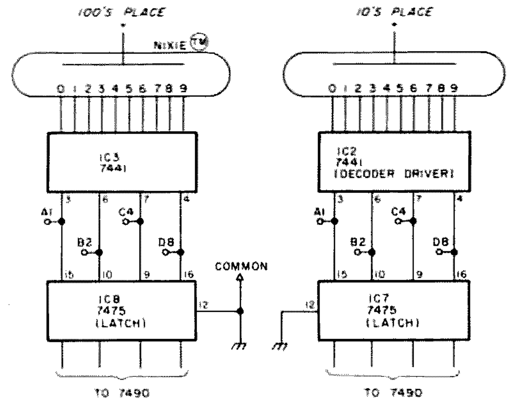

Fig. 2. Partial schematic of Heathkit IB1100 frequency counter showing where to connect inputs from audio decoder.

Optional Features

C2, Q2, and associated

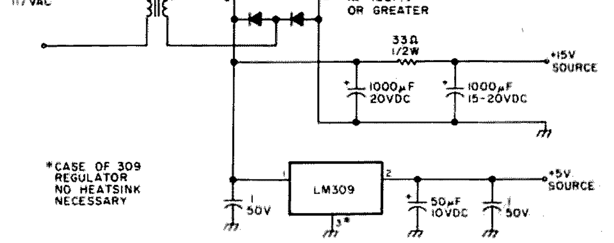

Fig. 3. 117 V ac input power supply for digital to audio decoder.

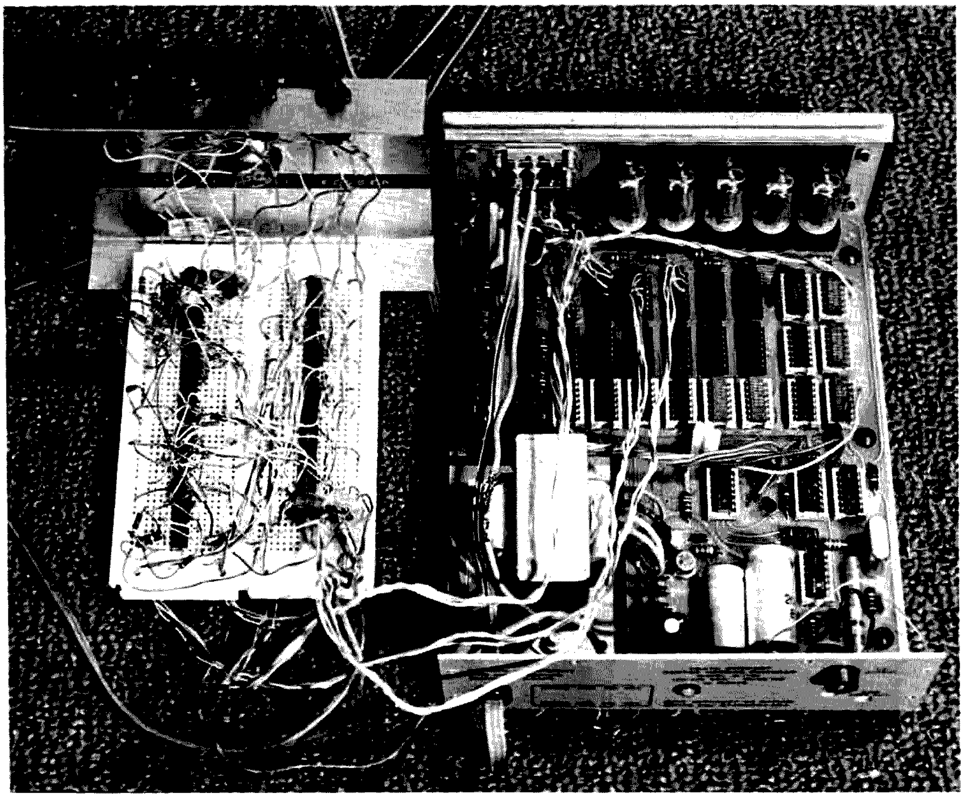

Photo 2. Audio decoder shown connected to Heathkit counter.

parts cause the speaker to emit a click every time the sequencer steps, thus announcing a new digit and serving as an audible "pilot light." IC11 and Q3 eliminate the zero tone, which you hear when the sequencer is stepping through unused outputs.

Speaking of unused outputs, enough are available to allow easy expansion up to eight digits, if desired. All you need to do is buy a few more 16¢ open collector NAND gates (7401s or 7403s), and string their outputs together in parallel with IC1, IC2, and IC3. Then duplicate the enabling circuitry used for IC1, IC2, and IC3, using the unused inverters in IC4 and IC8. Connect the inputs of these inverters to sequence generator point 4, point 5 and so on, depending upon how many additional digits you want. Remember, though, that these added digits are less significant than the first three, so connect the biggest place digit (100s, 1000s, 10,000s, etc.) to IC1. This ease of adding (or subtracting) digits is why I used lowly old open collector logic, as opposed to fancier data multiplexers. Be sure to connect all *used* sequence generator output points to an input of IC11, the 8 input NAND. Doing this allows the vco to turn on for all the digits you want. Unused IC11 gate inputs should be tied to +5 V (same as a "1" in TTL).

My last "optional" feature is probably not so optional. It gives the blind user the ability to hear what a number sounds like just by pushing the right combination of switches S1 through S8. For example, a "9" can be heard by pushing S1 and S8 simultaneously, or a "4" by pushing S4 alone. Pushing any of these buttons does a few other things, too. First, it removes power from IC1 through IC3, making all their outputs open up, allowing the pushed buttons to enter the desired number independently of the numbers being entered from the digital test instrument. Second, it brings one input of IC11 low, allowing the vco to function, so the tone can be heard. Finally, it stops the 555 timer from pulsing to allow hearing the tone alone. The switch marked S0 allows hearing the zero tone.

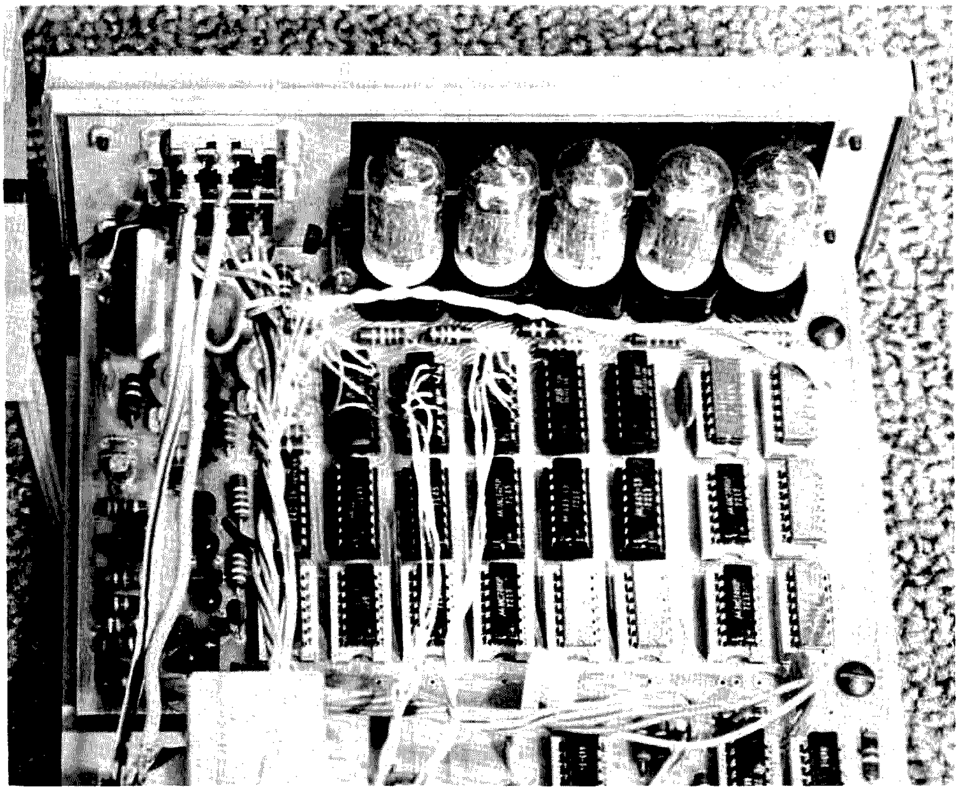

Fig. 3. 117 V ac input power supply for digital to audio decoder.

Interfacing

As it sits, this digital to audio decoder will not easily connect to every piece of digital test equipment, but it can be done! If the piece of test gear has an output connector labeled "BCD output," you're in. Most Heath frequency counters are usable, but you must solder to the circuit board. Connect the audio encoder's BCD inputs to test equipment's data latch outputs. Fig. 2 and Photo 3 show how this is accomplished for a Heath IB1100 frequency counter.

Construction

In that only eleven ICs and a few other parts are used, I don't think a printed circuit board is worthwhile. As to the mechanical details, like switch placement, I strongly urge you to talk it over with the person for which the audio decoder is intended.

As to operation, what can I really add? I went through most of it in the theory and optional features sections. When power is first applied, you should hear a clock every ½ second from the speaker, three tones after a few clicks, and then the same set of tones provided the numbers on the DVOM, counter, or whatever haven't changed. If you are in a hurry to try it out, as I was, you can take the 100s, 10s, and 1s input lines A1, B2, C4, and D8 and tie some high and some low. Be careful, though, not to exceed 9 on any digit, or the results could be a bit confusing to say the least!

Although there may not be anything in it for you, except satisfaction, please don't look at this as "just another project." Look at it in the light of letting a blind person see some of the numbers we take for granted. Build one for a friend. ■

MY PREDICTION

From everything that I can see so far, I would suggest that amateur radio in the 1980s may be almost entirely a VHF affair, with 50 MHz and 144 MHz as our major bands. I suspect that Cowan and S-9 may win the day with a CB band on 220 MHz, since hams seem to be doing very little to stop him. This is the chap who publishes *CQ Magazine*.

Without any satellite bands to mention, and without long-range communications, the whole fabric of amateur radio will change. About half of the active amateurs are already on two meters . . . now the other half will either join them or try stamp collecting . . . or computers.

IT IS NOT TOO LATE

Since most of the ITU countries have not yet formulated their positions on the shortwave bands, we still have some time, if we hurry, for ham ambassadors to lobby for our hobby. Members of the QCWA would seem to be ideal ham ambassadors. These are the people who made amateur radio what it is today and it would seem to rest in their hands to make amateur radio whatever it is going to be tomorrow.

The QCWA member amateurs include a great number of the pioneers and innovators — people with the drive and enthusiasm to get things done. It is not surprising to find that many of these same people have become top men in the electronics industry. As part of their work, many of these men travel quite a bit and have good opportunities to see the heads of foreign countries and put in a good word, or perhaps a few thousand good words, for amateur radio. A little side trip to see the king or president of a country will not generally hurt business, if I may be guilty of understatement.

No other group has such an elite membership as QCWA — just the type of people who could get an entry to a king and who would be able to sell the concept of amateur radio benefitting the country. Even if the ARRL wanted to spend money on such a project rather than their new million dollar wing of headquarters, they have no one of any stature to send out. Since QCWA members are already traveling, with their businesses paying the bills, there would be no cost to anyone for ambassadors.

QCWA members who are interested in the project should drop me a line and get a copy of a newsletter called "Amateur Radio, the Key to the Growth of a Country." There isn't much time to lose . . . unless you are a confirmed UHF addict and could care less about the low bands.

THE RADIO SHACK COMPUTER

"Most impressive" is my verdict on this one. When you see it and have a chance to try it out, you'll find it difficult not to like. They have packed a lot into what looks much like just a keyboard — it's the complete computer, with a Z-80 microprocessor, BASIC language on a ROM so it is right there ready to use as soon as you turn on the power, plus enough memory to tackle most things you might want to do. There is also the cassette interface system so all you have to do is plug in any ordinary cassette recorder to save and reload programs or data.

There are three sockets on the back panel of the computer — one for the monitor TV set, one for the little power supply which comes with it, and one for the cassette recorder.

The price for this? $400 for the computer, and $600 for the complete package of computer, TV monitor, and cassette recorder. Is it a coincidence that this is the same price as the PET?

Radio Shack's complete TRS-80 Microcomputer System, consisting of a 53-key professional-type keyboard and microcomputer plus regulated power supply, computer-controlled data cassette recorder, and 12" video display monitor, is suitable for business, educational, and home applications. Available exclusively from Radio Shack stores and dealers, nationwide, for $599.95.

Since I needed a computer system as a prop for a TV commercial I was making to advertise Computermania, I borrowed the computer and took it down to the TV station. Readers around the Boston area may have seen me operating it on the commercial, programming it to print out a short message for Computermania. The gist of the commercial was that here is a computer which would have cost over a million dollars just about ten years ago . . . now you can buy one for $400 . . . perhaps it is time to look into microcomputers for your business.

It's a very good-looking set and it worked like a charm.

It will be a while before production is up to full scale on this new system, so check into the larger Radio Shack stores from time to time. The first few production runs may go almost entirely by mail order, so you may have to buy one just to try it out . . . or at least keep an eye on your friends in case they buy one.

The BASIC which comes with the system is an abbreviated version in 4K of ROM. They are working on a more expanded version and that will probably accompany their disk system which is scheduled for December. Yep, disks are coming . . . starting with single density single side, about 90K of storage. You can be sure this will grow to double density, double sides, etc.

Synthesize Yourself!

-- practical experiments

Synthesizers are here to stay. Synthesizers are used in amateur and commercial transmitters, receivers, audio frequency generators, test equipment, and a multitude of devices for a large variety of purposes. They are used in applications that require the generation of a large number of frequencies.

Prior to the invention of the digital integrated circuit, synthesizers were few and far between. The technology was known, but the necessary fundamental building blocks were not readily available. Synthesizers were used, but they were cumbersome due to the large number of components required, and of course they were expensive to build and maintain. It wasn't until the advent of digital integrated circuits that synthesizers came into vogue because of the fact that digital ICs combined a large number of functions into a simple package. The "new" synthesizers are simple to construct, use few parts, and can by built inexpensively.

This article discusses the current generation of frequency synthesizers and provides an overview of the operation of the three common types of synthesizers in use today: the oscillator-mixer synthesizer, the period synthesizer, and the phase locked loop synthesizer. The greater portion of this article is devoted to the popular and versatile synthesizer, the phase locked loop, commonly known as the PLL synthesizer.

This article also describes simple synthesizer circuits and simple experiments using PLLs.

Those experimenters who are already experienced with synthesizers will notice that various topics have been glossed over or omitted in total. Those who have never worked with synthesizers should be able to read this article and make the simple circuits work.

Synthesis

Synthesis, by definition, is

a process that takes building blocks and produces a finished product. The process need not be complex, but may be very simple and be applied to a variety of applications. The average experimenter seldom gives thought to the definition of synthesis; however, the average experimenter commonly uses processes which fit the definition.

The process of summing two voltages to produce a third voltage (a process used in many pieces of electronic equipment) is synthesis, and the process of mixing two frequencies together to produce a third frequency (heterodyning in a receiver) is synthesis.

Oscillator-Mixer Synthesis

Fig. 1 is a mixing circuit of a simple superheterodyne receiver. Frequency F_1 (the heterodyning frequency) mixes with frequency F_2 (the incoming signal) to produce a frequency in the i-f range. This technique is not commonly thought of as synthesis, but is thought of as mixing; however, it is frequency synthesis.

In Fig. 2, a variable frequency oscillator, or vfo, of a transmitter is mixed with a heterodyning crystal to produce an output in a given band. In this case, the output frequency will be variable and is determined by the expression, $F_{out} = F_{vfo} + F_{crystal}$. If the frequency of the vfo can be varied from 5.0 to 5.5 MHz and the mixing crystal is 10.0 MHz, then the "synthesized output" will be in the range of 15.0 to 15.5 MHz. (Note that mixing produces both the sum *and* the difference frequencies, but in this example the difference frequency is filtered out.)

While a synthesizer of this type is very useful and very common, it suffers from a serious problem – the problem of stability. Vfos drift by nature, due to temperature fluctuations, and are subject to frequency variation due to vibration and the inadvertent bumping of the vfo dial. (And, of course, it is difficult to reset the dial back to its original position once it has been bumped.) Fig. 3 shows an improved version of the simple "synthesizer." In this example, the vfo is replaced with another crystal oscillator and a crystal switch. In the example given, ten crystals spaced 10 kHz apart are mixed with the heterodyning crystal to produce ten discrete frequencies in the 15 MHz range, 10 kHz apart. The spacing of the output frequencies is called "channel spacing," and is related to the channel spacing of the "local oscillator" crystals.

The drawbacks to the circuit shown in Fig. 3 are very obvious. First of all, eleven crystals are needed to produce ten frequencies, and second, the output frequencies are limited to discrete frequencies or channels. Furthermore, all frequencies within a given band are not covered. From a cost standpoint, it would be better to use ten crystals at the desired frequencies than to use this circuit.

Fig. 4 is an improved version of the synthesizer shown

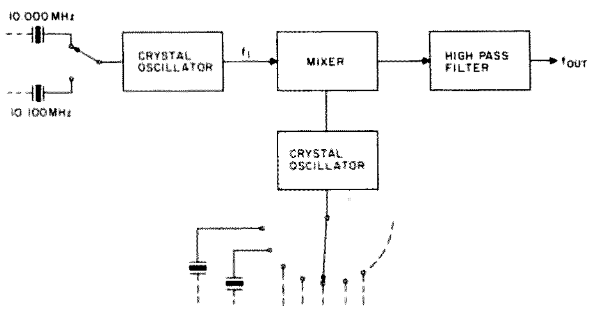

Fig. 4. Twenty frequency crystal-mixer synthesizer.

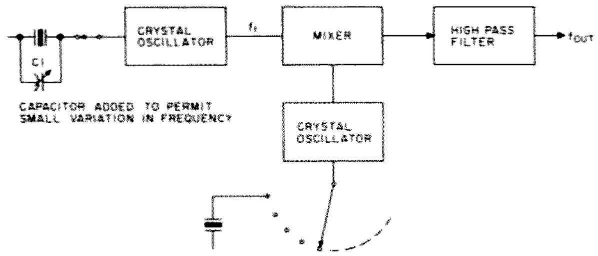

Fig. 5. Varying the frequency of a crystal-mixer synthesizer.

Fig. 6.

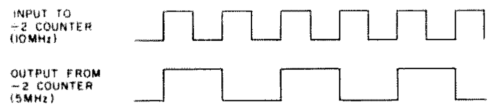

Fig. 7.

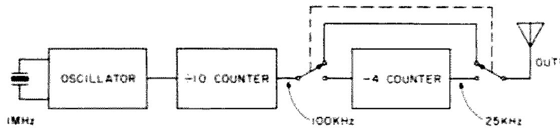

Fig. 8.

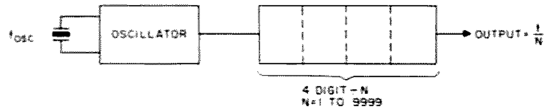

Fig. 9.

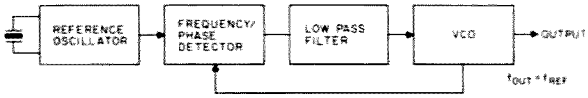

Fig. 10.

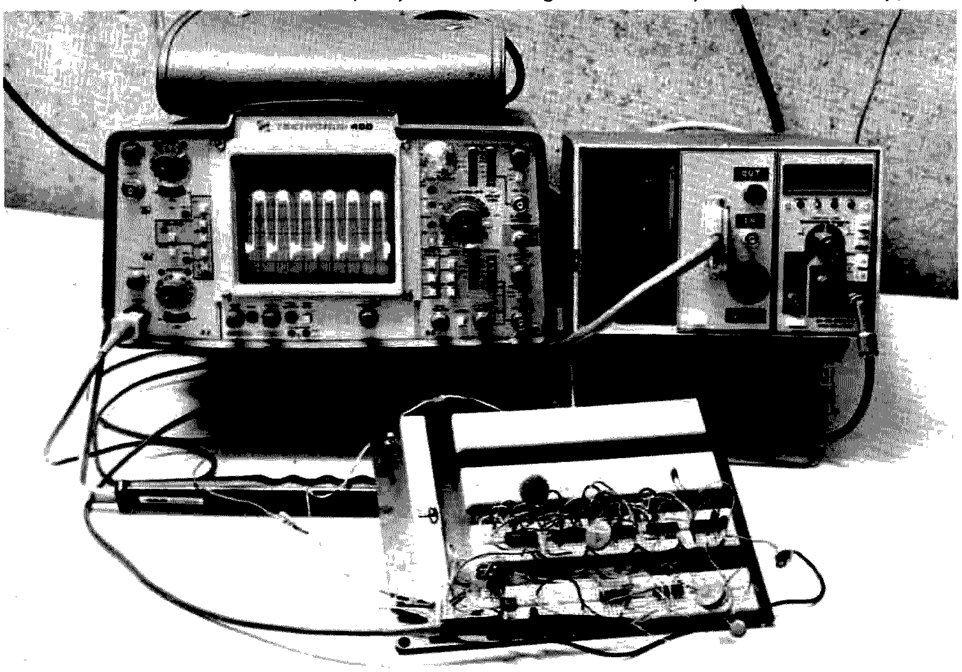
in Fig. 3. In this example, two heterodyning crystals are used, F_1 = 10.000 MHz and F_2 = 10.100 MHz. Table 1 shows the output frequencies that can be obtained by mixing the two heterodyning crystals with the ten local oscillator frequencies.

Note that in this case we are using twelve crystals to generate twenty discrete frequencies. At this point we have an economical alternative to the use of twenty crystals to generate twenty discrete frequencies. We have a saving of eight crystals. If we add a third heterodyning crystal, we can generate thirty discrete frequencies with thirteen crystals and save ourselves seventeen crystals. This process can be continued by adding heterodyning crystals to the point where all desired frequencies within a given band are generated; however, at $5.00 and up per crystal, the designer soon reaches the point where a crystal-mixing synthesizer is not economically feasible. This type of synthesizer is useful in cases where it is desirable to generate a limited number of stable, discrete frequencies in a simple manner.

The other drawback of the crystal-mixing type of synthesizer, as previously mentioned, is the problem that the output frequencies are discrete and that all frequencies within an entire band are not covered. Gaps occur in the frequency coverage of the unit. In many cases, such as VHF radiotelephone, this is not a serious drawback (since operation in the VHF radiotelephone bands is channelized to begin with); however, in the case of high frequency operation where fixed channels are not used, discrete frequency operation can present a problem. Fig. 5 shows a simple cure to permit continuous operation in the areas between channels. The trimmer capacitor C_1, across the crystal, is varied and produces a small frequency variation of the frequency of the heterodyning crystal. If the channel spacing is small, the trimmer can permit coverage of all frequencies between channels. The addition of this trimmer does reduce stability a bit, but this reduction in stability in most cases is not too serious.

The crystal-mixing type of



Test setup at W1HCI used for testing 3 to 9 MHz synthesizer. The scope trace shows ringing and noise on the vco signal, due to the random component layout and long lead lengths on the breadboard.

synthesizer is commonly used in amateur and commercial HF and VHF equipment; however, it is becoming less popular due to the high cost of crystals and the availability of the phase locked loop. Furthermore, some of these synthesizers that have been on the market in the past have suffered from a variety of problems and become somewhat unpopular. In some cases it was possible to have several crystals oscillating at one time, producing multiple output frequencies. (Of course, this problem could be put to good use if the operator desired to transmit on several frequencies simultaneously.)

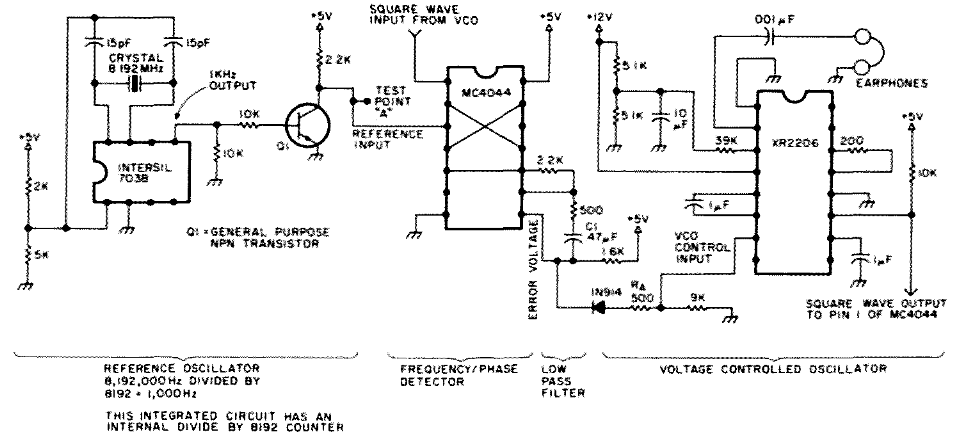


Fig. 11. Simple phase locked loop.

Time Period Synthesis

Time period synthesis, according to some authors, encompasses a variety of techniques, including the phase locked loop. In this article, however, time period synthesis will be defined as a counting technique that generates a waveform with a time period proportional to some "N" number of counts of a standard oscillator. As an example, consider the crystal oscillator in Fig. 6 that feeds a digital divide by two counter. The divide by two counter generates one output pulse for every two input pulses. This is shown graphically in Fig. 7. This is a simple time period synthesizer. If the crystal operates at 10 MHz, then the output from this simple synthesizer will be 5 MHz. This technique is used frequently in crystal calibrators found in many pieces of amateur equipment. Fig. 8 shows a block diagram of a typical calibrator. In this block diagram, a 1 MHz oscillator is fed into either a divide by ten or a divide by ten followed by a divide by 4. The outputs are either 100 kHz or 25 kHz. If a series of digital counters were connected together to form a four digit, divide by N counter, as shown in Fig. 9, then a versatile time period synthesizer could be constructed to produce a large number of frequencies.

One of the drawbacks of time period synthesis is that switch selection (in the divide by N counter) programs the number of counts to divide by, and the number N is not the frequency. The expression for frequency for the time period synthesizer is

$$F_{out} = \frac{f_{osc}}{N}$$

where f_{osc} is the frequency of the standard oscillator.

Note that the frequency is inversely related to the number N. Table 2 gives a list of frequencies for selected values of N.

It is not possible to get standard channel spacing when incrementing N. When N is changed from 51 to 52, the frequency difference or channel spacing is 37,707.4 Hz, but when N is changed from 1001 to 1002, the spacing is 99.701 Hz. The channel spacing is not linear, and produces low frequencies for high values of N (in this case, frequencies in the audio range). Synthesizers of this type are difficult to use for most amateur applications.

One notable use of this type of synthesizer is found in the common "touchtone" generator ICs. These ICs provide a fixed series of dividers used to divide a master oscillator down to the proper audio frequency.

The Phase Locked Loop

The fundamental phase locked loop, as shown in Fig. 10, consists of a frequency standard or reference oscillator, a voltage controlled oscillator, a frequency/phase detector, and a low pass filter. In operation, the frequency and phase of the frequency standard is compared against the output of the voltage controlled oscillator. If there is a difference in frequency or phase, then an output voltage, or error signal, is produced by the frequency/phase detector. This output voltage is fed back into the voltage controlled oscillator to change its frequency. This fundamental phase locked loop is used to synchronize two oscillators together, and is not commonly used in amateur equipment in this fundamental form. This simple example can, however, be

f_1	f_2	f_{out}

used as a basis for understanding the PLL and some of the problems that occur in PLL operation.

The Reference Oscillator

The reference oscillator, or frequency standard, for a PLL system must be of high stability and is usually a crystal oscillator. This crystal oscillator may be used by itself, or it may be used in conjunction with a series of frequency dividers to produce a given output frequency. In the case where a series of dividers follows the crystal oscillator, the reference oscillator is in itself a "time period" synthesizer. The output of the reference oscillator is a determining factor in the channel spacing of the synthesizer, and, in the case of the synthesizers discussed in this article, is the same as the channel spacing.

Fig. 11 shows the circuit diagram for a simple reference oscillator. In this example, an 8.192000 MHz crystal is the frequency determining element and is followed by a divide by 8192 stage. The output of the reference oscillator is 1,000 Hz. The 7038 integrated circuit consists of an oscillator and an internal divide by 8192 counter.

The Vco

A voltage controlled oscillator, or vco, is a special version of a vfo. In a vfo, the frequency is changed by manually moving the rotor of a variable capacitor or by manually moving the slug in a variable inductor. In a vco, the frequency is changed by applying a voltage to a device such as a variable capacitance diode in an oscillator circuit or by changing the bias on a multivibrator. A change in voltage will produce a change in frequency of the oscillator.

While the experimenter may build a vco from discrete components, it is convenient to use integrated circuit vcos such as the Motorola MC4024 voltage controlled multivibrator or the Exar XR-2206 monolithic function generator.

The Motorola MC4024 will operate from audio frequencies to 25 MHz, produces a square wave output, and has a maximum control range of 3.5 to 1. The XR-2206 will operate from .01 Hz to 1 MHz, produces either square, triangle, or sine waves at the output, and has a maximum control range of 1000 to 1.

The control range of a vco (also called the sweep range) is defined as the ratio of the highest frequency to the lowest frequency that can be obtained by varying the control voltage while keeping all external components the same. For example, Fig. 11 shows an XR-2206 monolithic function generator configured as a vco to produce audio frequencies in a PLL. By varying the control voltage in this circuit, the output frequency will change from about 400 Hz to about 9500 Hz, for a control range of about 23 to 1.

The Frequency/Phase Detector

The frequency/phase detector is used to compare the output of the vco against the output from the reference oscillator. A typical frequency/phase detector is the Motorola MC4044. While the internal operation of this device is somewhat complex, the results of what it does are easy to see and understand.

Fig. 11 shows an MC4044 frequency/phase detector connected in a PLL. The low pass filter in this circuit is used to smooth the output and eliminate high frequency components in the output.

In this example, if the vco frequency is greater than the reference frequency, then the output will be in the range of about 2.5 to 5 volts. If the frequency is less than the reference voltage, then the output will be in the range of 2.5 to .8 volts.

As the name implies, the frequency/phase detector also detects phase differences between two signals. Consider the case where two signals are at the same frequency but are slightly out of phase with each other. In this case, there will also be an output voltage from the frequency/phase detector. This output voltage is a "phase error" voltage, and will remain constant when the loop is "locked," or in a stable condition. When the loop is not "locked," as when the frequency of the vco is in the process of changing, then this error voltage will be changing. Note that the error voltage may also remain constant if the loop is unable to lock up.

The Fundamental PLL

Fig. 11 shows a circuit diagram for a simple PLL operating in the audio range. This circuit is a good circuit to use for experimentation, since the output is 1 kHz to 9 kHz in the audio range. A pair of earphones may be used on the output to determine if the circuit is operating correctly. An oscilloscope or counter is *not* needed to experiment with this PLL.

To use this circuit for experimentation, first disconnect the square wave output from pin 1 of the MC4024, and then connect the +5 V and +12 V as shown. Connect the earphones to test point A through a .01 uF capacitor. A 1 kHz tone, rich in harmonics, should be heard in the earphones. At this time, the output of the vco will be at about 9.5 kHz, the idling frequency of the vco. Now connect the earphones to the output of the vco, as shown on the schematic. Connect the square wave output of the MC4024 as shown. The output of the vco will change from 9.5 kHz to 1 kHz. Note that it is possible in this example for the PLL to lock to a frequency that is a multiple of 1 kHz, since a PLL can lock to a harmonic or subharmonic of the reference frequency. This property is useful for some applications; however, it would not be useful for amateur applications such as a two meter PLL.

It is difficult to explain the reasons for harmonic or sub-harmonic locking in simple terms. From a practical standpoint, this type of locking can occur due to poor design, or if the tuning range of the vco is too great. In this example, the potential problem of harmonic or subharmonic locking could be eliminated by limiting the tuning range of the PLL. A good rule of thumb is to limit the tuning range of the PLL to 3.5 to 1 or less.

Readers who wish to go into the fine details of the operation of frequency/phase

N	D	C	B	A

Table 3.

detectors, vcos, and PLLs in general are referred to reference 1. This reference gives a detailed, authoritative explanation of PLLs.

An "N" Channel PLL Synthesizer

The previous "simple PLL" might be called a single channel synthesizer, since its output is on a single channel and cannot be varied from that single channel. A more versatile synthesizer is shown in the block diagram in Fig. 12. This is a one digit "N" channel synthesizer where N can range from 1 to 9. The PLL is the same as the simple PLL, except that a divide by N counter has been placed between the vco and the frequency/phase detector. In operation, the PLL will increase the frequency of the vco such that the output of the vco divided by N is equal to the reference frequency. Thus the output of the vco is "N" times the reference, where N is an integer. If we modify Fig. 11 by adding a divide by N counter as shown in Fig. 13, we will have an N channel synthesizer where the theoretical output range would be 1 kHz to 9 kHz in 1 kHz steps, when N goes from 1 to 9.

As previously mentioned, PLLs can lock to the wrong harmonic if the tuning range of the PLL is too great. In this example, the tuning range of the PLL is about 9.5 to 1. The problems with the tuning range can be demonstrated by performing some very simple experiments with the "N" channel PLL. Again, these experiments can be performed with the use of earphones. A scope or counter is not required, but may be used if desired.

The 74192 divide by N counter can be programmed in BCD format to provide an N of 1 to 9. To program a number, first set all inputs to 0 by grounding. A number is programmed by setting a "1" into an input, according to Table 3. A one is set by connecting the input to +5 V through a 1k resistor.

To experiment with this simple PLL, first connect the earphones as shown. Next, program a 1, to get a 1 kHz tone, as shown in Fig. 14. A 1 kHz tone will be heard. Next, program a 2, 3, and 4, one at a time. Tones of 2, 3, and 4 kHz will be heard. This simple PLL should lock up for these values of N on the correct multiples of 1 kHz, but will probably not lock up for some other values of N. For example, when N = 5, the PLL may lock up on 1 kHz, and when N = 7, it may lock up on 3 kHz. This is an example of a PLL with too great a range. Changing R_a to a value of 1k will limit the range of the loop to about 4 to 1, just slightly greater than the recommended range. With this limit imposed, the loop will lock properly in the desired range of 1 to 4 kHz. An N of greater than 4 will give an output of about 4.7 kHz, and the loop will not be locked. In some cases, it may be necessary to wire in external logic or put limits on switches to prevent the "dialing in" of non-allowed values of N on the switches and the resultant locking to wrong frequencies.

Other Design Considerations for PLLs

While it is not possible in a short article to give complete design information and describe all design considerations for a PLL, there are some key points which must be mentioned.

In the general description of the components of the PLL, the filter was mentioned only briefly. The filter is an important part of the PLL, and must be chosen such that the loop locks up quickly but

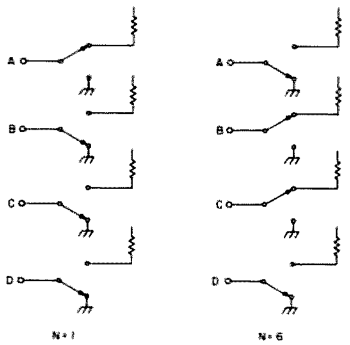

Fig. 14. Examples of programming the ÷N counter.

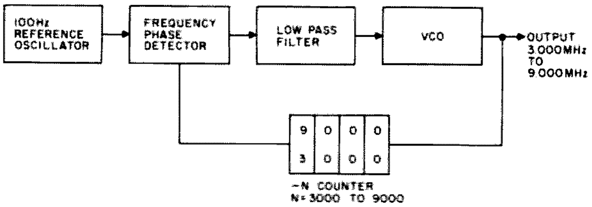

Fig. 15. HF PLL.

still filters out all high frequency components. If the filter is not correct, the loop could be too slow to respond, not operate correctly (producing distorted waveforms), or not lock properly. The value of the capacitor in the low pass filter may be determined experimentally by observing the control voltage on an oscilloscope. C_1 should be chosen just large enough so that the control voltage is pure dc with very little ripple. If a scope is connected to pin 8 of the MC4044 and C_1 is removed, the effects of poor filtering can be observed. High frequency components will be observed on the vco control line, and the output waveform will be distorted. (Reference 1 should be consulted for detailed filter requirements.)

Another consideration for a PLL is the stability of the oscillator. If the oscillator drifts, then the output will drift according to the following expression: $f_{output\ drift} = N \times f_{reference\ drift}$. For example, if the reference drifts by +10 Hz and N = 4, then the output will drift by +40 Hz.

Noise on the vco line can sometimes cause problems. These problems can be reduced by designing the vco so that a relatively large change in control voltage is required to produce a relatively small percentage frequency change. In addition, it is important to sprinkle bypass capacitors liberally from the +5 V, +12 V, or other voltage lines to ground. A good practice is to place a .01 capacitor from the +V terminal of each IC to ground, keeping the leads as short as possible.

Rf can be a problem with PLLs. If rf sneaks into the wrong place within a PLL, the PLL can fail to lock or can lock at the wrong place, the vco can cease to operate, or a myriad of other problems can result. For these reasons, it is important to shield a PLL that is used with a transmitter, to prevent rf from the transmitter from getting back into the PLL synthesizer.

It is also important to remember that PLLs have square waves, rich in harmonics, coming out of the reference as well as the divide by N circuitry. These square waves can cause interference in nearby receiving equipment. It is important to shield a PLL synthesizer to prevent interference to other equipment.

A Synthesizer for the HF Bands

The synthesizer examples

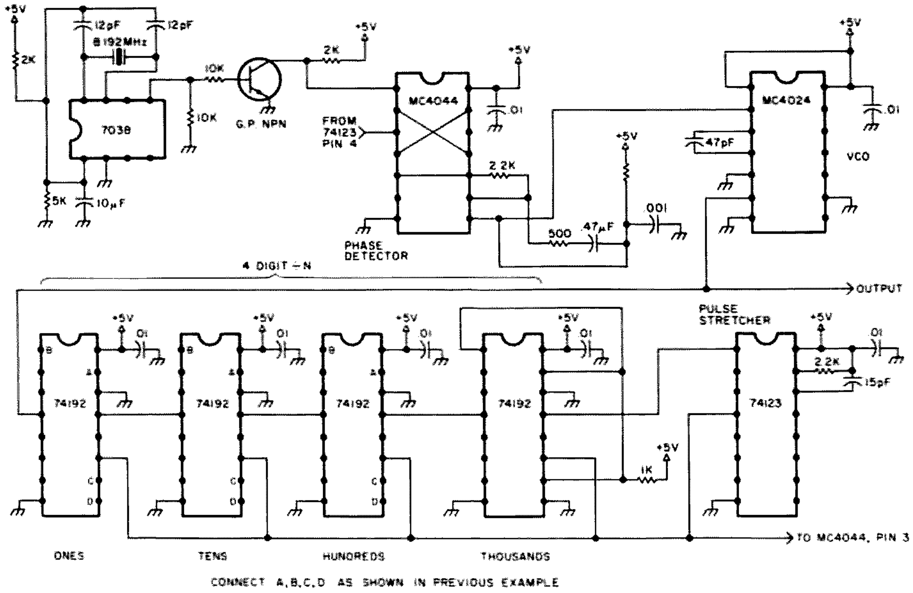

Fig. 16. HF synthesizer.

previously described operated in the audio range, a range ideally suited for experimentation. Synthesizers of general interest to the amateur may lie in the HF region. This section will discuss HF synthesizers.

In designing a synthesizer for HF use, two criteria must first be defined:

1. Output frequency range;
2. Channel spacing.

Consider an example where a synthesizer is required to operate with an output in the range of 3 to 9 MHz in 1 kHz steps. In this case, our PLL will have a range of about 3 to 1. The channel spacing would be 1 kHz, so the output of the reference oscillator must be 1 kHz. In all "direct" PLLs, a PLL where the output is used directly without mixing or multiplication of the output, the channel spacing is the same as the reference frequency. For other types of synthesizers, such as VHF synthesizers (where the output of the PLL is fed into a multiplier stage), the reference frequency is determined by the expression, $f_{reference}$ = (channel spacing)/(total multiplication in multiplier stages). The range of this PLL synthesizer is to be from 3 to 9 MHz. Converting these numbers to kHz, we get 3000 to 9000 kHz; thus, for 1 kHz channel spacing, N would have to range from 3000 to 9000. As can be seen, we require four digits for N. Thus, our divide by N counter would be a four digit divide by N counter.

Fig. 15 shows a block diagram for this PLL. Since the formula for a PLL is $f_{out} = N \times f_{reference}$, and since N can be any number from 1 to 9999 in this example, it seems likely that switches could be set so that N is outside of the desired range of 3000 to 9000. If N is set below the desired range, the vco will idle, but it will not lock at the lower limit of the vco. Likewise, if N is set above the desired range, then the vco would run at this upper limit. In some cases, a value of N outside the range can cause a PLL to lock on an incorrect frequency. Thus, it is a good idea to limit the allowable switch positions either electronically or mechanically. In the example shown in Fig. 16, the most significant digit is hardwired to a 7, so this synthesizer is electronically limited to the range 7000 to 7999. This limit is arbitrary, and may be changed if desired. If the experimenter wishes, the most significant digit could be varied in the same manner as the other three digits.

Fig. 16 is a circuit diagram of a 7.000 to 7.999 MHz synthesizer. This synthesizer can be breadboarded in an evening, and should work the first time it is turned on. Each digit is programmed in BCD in the same manner as the simple audio PLL, except that the first digit is hardwired to a seven and does not change. As previously mentioned, the number 7 was chosen arbitrarily and may be changed. The vco in this PLL is a Motorola MC4024, which generates a square wave output. If a sine wave output were desired, then either a low pass filter would have to be placed on the output of the vco (to eliminate all frequencies above 7.999 MHz, for example), or a different vco would have to be used.

Note that this synthesizer radiates a lot of rf noise, so expect some possible interference in nearby receiving equipment.

The frequency output of this synthesizer may be measured on a counter, or its signal may be heard on a communications receiver. The sound of the signal as heard on a communications receiver will not be pure, due to the fact that this PLL uses a simple loop filter, which allows some inherent modulation of the signal. Furthermore, the PLL divider stages and reference will radiate, causing noise in the receiver. Shielding will improve the sound of the signal, but will not make it perfect.

The 74123 is a monostable multivibrator and is provided to lengthen the reset pulse generated by the divide by N circuitry. When the divide by N circuitry counts to the programmed value, a reset pulse is used to reset the counters so that they may start counting again. For the 74192 ICs, this reset pulse must be at least 20 nanoseconds long to insure proper resetting. During this 20 ns reset period, the counters are not counting. At 7.5 MHz, the time from one cycle of the vco to the next would be 130 ns. If this time period from one cycle to the next of the vco is less than twice the reset time (in this case 40 ns), a missed count will occur, causing the output frequency to be off by one (in the least significant digit). This holds true in cases where the vco generates a square output. In cases where the vco generates sine waves to other waveforms, the period of the vco may have to be greater than the reset time by a factor of 4 or more.

If a missed count does occur, circuitry can be added to automatically compensate for the missing count.

Summary

This article has described the operation of synthesizers and has given simple circuits for experimentation. It is not meant to be the last word in synthesizers, but is meant to whet the appetite of the experimenter. The experimenter is encouraged to read the references given to gain a greater comprehension of the subject. ■

Social Events

ERIE PA
SEPT 25

The 2nd Annual Erie HamJam will be held Sunday, September 25, 1977 at Rainbow Gardens, Waldameer Park. Door prizes, flea market, forums, large indoor facilities. For more information write Radio Association of Erie, Inc., PO Box 844, Erie PA 16512.

NEW BERLIN IL
SEPT 25

The Sangamon Valley Radio Club will hold its Second Annual Hamfest on Sunday, September 25, 1977 at the Sangamon County Fairgrounds, New Berlin, Illinois, 16 miles west of Springfield. Indoor display area and a covered pavilion. Food, refreshments, exhibits and ladies' activities. Overnite camping on grounds. Tickets $1 advance; $1.50 at gate. First prize – Wilson HT. Talk-in 146.28/.88 and .52. Info: Carole Churchill WB9QWR, 622 Magnolia, Rochester IL 62563.

BROOKLYN NY
OCTOBER

The Kings County Repeater Association of Brooklyn, New York, announces the formation of its second Novice class licensing course (theory and code) to begin in October. Contact Carl Weintraub W2YHX, 629 Avenue "T", Brooklyn NY 11223 for full details.

WILLOW GROVE PA
OCT 1

The Mid-Atlantic States VHF Conference will be held on Saturday, October 1, 1977 at the Treadway Inn on Easton Road (Route 611, Exit 27 of the Pennsylvania Turnpike) in Willow Grove, Pennsylvania on the day before Hamarama 77 (at nearby Warrington, Pennsylvania). The conference will be an all day VHF program moderated by prominent VHFers. Advance registration is $2.50 (includes admission to Hamarama 77 on Sunday). Cocktail hour (cash bar) and get-together at 6:30 pm. Buffet dinner at 7:30 pm is $8.00. Special rates for rooms overnight. For advance registration contact Ron Whitsel WA3AXV, Chairman, PO Box 353, Southampton PA 18966, phone (215) 355-5730. Advance registration must be received by September 28, 1977. Indicate motel registration forms required.

HAMDEN CT
OCT 1

The Oktoberfirst Flea Market and Auction will be held October 1, 1977 (rain date Oct. 8). The event, sponsored by the WELI Amateur Radio Club (WA1HRC), will be held at Radio Towers Park, Benham Street, Hamden, Connecticut. Free admission, vendor spaces are $5/ea. Talk-in on 52 direct or 01/61. More information call Doug WA1TUT (203) 389-6458.

MEMPHIS TN
OCT 1-2

The Memphis Hamfest, bigger and better than the 4,500 who attended last year, will be held at State Technical Institute, I-40 at Macon Road, on Saturday and Sunday, October 1 and 2. Demonstrations, displays, MARS meetings, flea market, ladies' flea market, too! Hospitality Room, informal dinners, XYL entertainment, many outstanding prizes. Dealers and distributors welcome. For further information contact Harry Simpson W4SCF, PO Box 27015, Memphis, Tennessee 38127.

CEDAR RAPIDS IA
OCT 2

The Cedar Valley Amateur Radio Club annual Hamfest will be held Sunday, October 2, 1977. Top prizes are Atlas 210X Xcvr, Wilson 1402 SM H/T, Heathkit HW-8 QRP CW Xcvr, Clegg FM-76 Xcvr, plus much more. Technical talks featuring Doug DeMaw W1FB. Manufacturers and dealers welcome. Talk-in on 146.16/.76, 146.52, 3.970, and 223.5 MHz. Advance tickets $1.50, $2.00 at the door. Write CVARC Hamfest, Box 994, Cedar Rapids IA 52406.

NEWPORT NH
OCT 2

Autumnfest, the first annual hamfest of the Connecticut Valley FM Association, will be held on October 2, 1977, at the Community Center, Belknap Ave., off Rt. 10, north end of the Common. Flea market opens at 9 am – auction at 2 pm. Program includes antenna gain contest, fox hunt on 52 simplex, frequency and modulation checks by W1RNZ, and talks and demonstrations throughout the day. Donation: $1.50 in advance – $2.00 at the door. Talk-in on 16/76 or on 52 simplex.

WARRINGTON PA
OCT 2

The Mt. Airy VHF Radio Club (the Packrats) are holding "Hamarama 77" at the Bucks County Drive-In Theater, Route 611 (Easton Road), Warrington, Pennsylvania on Sunday, October 2, 1977, 8 am to 4 pm rain or shine. Registration $1.50, tailgating $2.00/space (bring your own table). Talk-in via W3CCX/3 on 52.525 and 146.52, WR3ACD on 222.98/224.58, WR3ADS on 147.63/147.03, and WR3AHC on 147.60/147.00. Advance registration to the Mid-Atlantic States VHF Conference includes admission to Hamarama. For information contact Ron Whitsel WA3AXV, Chairman, PO Box 353, Southampton PA 18966, phone (215) 355-5730.

BERRIEN SPRINGS MI
OCT 2

The Blossomland annual fall Swap-Shop will be held Sunday, October 2 at the Berrien County Youth Fairgrounds, Berrien Springs, Michigan. Large and convenient facilities, prizes, refreshments, and fun. Open all night for setup. Table space restricted to radio and electronic items. Advance ticket donation $1.50. Tables $2. Talk-in 22/82 and 94. Write John Sullivan, PO Box 345, St. Joseph MI 49085. Make checks payable to Blossomland Hamfest.

EAST RUTHERFORD NJ
OCT 8

The Knight Raiders VHF Club, K2DEL, presents its world famous Auction & Flea Market to be held at St. Joseph's Church of East Rutherford, New Jersey, Saturday, October 8, 1977 beginning at 10 am. Free admission – free parking. Flea market tables (in advance) $5 full table, $3 half table; (at door) $6 full table, $3.50 half table. Directions: take Rt. 17 north from Rt. 3 to East Rutherford, exit onto Paterson Plank Road, follow to traffic light with Diner on the corner, make sharp right, follow for one block, at light you will see St. Joseph's Church on your right, make right turn at corner and enter parking lot. For further information call: Bob Kovaleski (210) 473-7113, evenings only. Talk-in on 146.52. Send reservations and make checks payable to: Knight Raiders VHF Club Inc., PO Box 1054, Passaic NJ 07055 (reservations close October 1).

SHREWSBURY MA
OCT 8-9

The Heart Fund Hamboree (all proceeds to be given to the Heart Fund) will be held on October 8 and 9, 1977, at Simeon's Park on Route 9 in Shrewsbury MA. Program includes door prizes, trophies, special prizes and entertainment. For advance tickets send $1.50 donation (orders must be received by Sept. 15) – $2 donation at gate. Senior citizens and children 12 years or under free. For dealer space and ticket information write: Central Mass. 2-Way Radio Assoc., P.O. Box 154, Northboro MA 01532.

SYRACUSE NY
OCT 8

The Radio Amateurs of Greater Syracuse presents the Syracuse Hamfest, October 8, 1977 from 9 am to 5 pm at the Syracuse Auto Auction, Route 11, Nedrow, New York. Easy access from Route 81, 5 miles south of Syracuse. Food available all day at reasonable prices. Large exhibitor area and flea market under cover. Exhibitors: $13.00 (includes one 8-foot space, 8-foot table, two chairs and admission to hamfest). For further information: general info – RAGS Hamfest, Box 88, Liverpool NY 13088; exhibitors – Dale Mecomber WB2FJC, Box 87, Skaneateles Falls NY 13153.

YONKERS NY
OCT 9

The Yonkers Amateur Radio Club is holding "Super Hamfest 77" on October 9, 1977 (rain date Oct. 16) from 9 am to 5 pm at Redmond Field, Cooke Avenue in Yonkers. Manufacturers' displays, door prizes, raffles, refreshments and a general auction are all in store. Buyers $1, sellers $3 – bring your own table. Talk-in 146.265, 146.865, 146.52 simplex. For further information contact Doug McArtin WA2AUJ, 411 Bellevue Ave., Yonkers NY 10703, (914) 423-0515.

WINDSOR LOCKS CT
OCT 14-16

The Region 1 Air Force MARS Convention will be held on October 14, 15, 16, 1977 at the Howard Johnson's Conference Center, Center Street Exit I-91, Windsor Locks, Connecticut. *73* publisher Wayne Green will be guest speaker.

SAN MATEO CA
OCT 15-16

The Greater Bay Area Hamfest and ARRL Pacific Division Convention will be a combined event this year held on Saturday and Sunday, October 15 and 16, at the Royal Coach Inn, centrally located on the San Francisco Peninsula just off the intersection of U.S. 101 and Route 92 in San Mateo. For more information contact the Greater Bay Area Hamfest, Box 751, San Mateo CA 94401.

TAYLOR MI
OCT 16

The Repeater Association of Downriver Amateur Radio (R.A.D.A.R.) Hamfest will be held on October 16, 1977, at the Kennedy High School located in Taylor, Michigan, on Northline Road, east of Telegraph (U.S. 24). Door prizes and food. Admission $2.00/YLs free. Reserved tables $1. Open 9 am until 3 pm. Talk-in will be on 52-52, 34-94, 93-33. For further info write: R.A.D.A.R., Inc., PO Box 1023, Southgate, Michigan 48195.

ISLIP NY
OCT 16

Hamfest and Giant Swap & Shop sponsored by LIMARC, the Long Island Mobile Amateur Radio Club, will be held on Sunday, October 16, 1977, at the Islip Speedway, Islip, New York. Gates open at 9:30 am to 4 pm. General admission $1.50 (wives, children and sweethearts, free). Exhibitors and swappers $2.50 per car

space. Featuring: amateur radio, CB, computer, amateur television, satellite, ARRL info, theory contest, LIMARC tune-up clinic, awards and door prizes. Located on Route 111, Islip Avenue, one block south of Exit 43 of the Southern State Parkway; trucks, campers and trailers use the Long Island Expressway Exit 56, Rte. 111, south to the speedway. For more information: Hank Wener WB2ALW, days (212) 355-0606, nights (516) 484-4322.

VALPARAISO IN
OCT 16

The new Annual Valpo Tech Hamfest and Fleamarket is Sunday, October 16, 1977, 7 am to 3:30 pm, on the Valparaiso Technical Institute campus, located on Lincolnway (US 130) at Yellowstone Road, west of downtown Valparaiso, Indiana. Held on the day after Valpo Tech Homecoming. Prestigious electronics school offering large storerooms of surplus test instruments, digital equipment, computer circuits, transmitter components, TV equipment, semiconductors, and much more, at give-away prices. Everything must go to make room for new labs. No charge for setup space. Room inside in case of rain. Hourly drawings beginning at 8 am for prizes. Main drawing at 2 pm. Talk-in on 146.94 MHz. Tickets $1.50 advance, $2.00 at the door. For advance tickets send $1.50 each and an SASE to Dale E. Smiley WB9SFF, Operations V-P, Valpo Tech Alumni Association, Box 490, Valparaiso, Indiana 46383.

WAKEFIELD MA
OCT 22

The Quanapowitt Radio Association will hold its annual auction in St. Joseph's Parish Hall, Wakefield MA on Saturday, Oct. 22, 1977. Doors open at 10 am, auction starts at 11 am. Ten percent commission, no minimums. Talk-in on 146.52.

GAITHERSBURG MD
OCT 23

The Foundation for Amateur Radio will hold its annual hamfest at the Gaithersburg Fairgrounds, Gaithersburg, Maryland, on Sunday, October 23, 1977. Featured is a large flea market, food service, exhibits, ladies' events, supervised children's program, and many prizes. Main events are all indoors. Picnic grounds and free parking available; will be held rain or shine; participation fee is $2.00; sales space for flea market is $5.00 each on a first come basis; commercial exhibitors $10.00 each, with preregistration required prior to October 20th. For more information, write or call Hugh Turnbull W3ABC, 6903 Rhode Island Avenue, College Park, Maryland 20740, telephone (301) 927-1797.

FORT LAUDERDALE FL
OCT 29-30

The "International" Pan-American Ham/Exposition Jamboree will be held on October 29 and 30, 1977. Welcome: CB, ham and marine. For further information contact: Broward Amateur Radio Club, Capt. S. F. "Red" Crise (Show Chairman) WA4ZRW, 3701 State Road 84, Fort Lauderdale FL 33312.

PLYMOUTH IN
OCT 30

The Radio and Electronics Swap and Shop, sponsored by the Marshall County Amateur Radio Club, will be held on Sunday, October 30, 1977, at the Plymouth, Indiana National Guard Armory, located at 1220 West Madison Street, from 8 am to 5 pm. Free tables, no charge for setup. Tickets $2 at door. Food, drink and door prizes. Talk-in on 146.07-67 and 146.52 simplex. For further information contact Wayne Zehner WA9INM, Rt. 3, Box 526, Plymouth IN 46563.

CLEARWATER BEACH FL
NOV 19-20

The Florida Gulf Coast Amateur Radio Council is holding its 2nd annual convention on November 19 and 20, 1977 at the Sheraton Sand Key Hotel on Clearwater Beach FL. Official attendance at our last affair was placed in excess of 2200, and this year we expect to double that number as we increase the number of activities and size of the convention. For more information contact: Florida Gulf Coast Amateur Radio Council Inc., PO Box 157, Clearwater FL 33517.

ELLICOTT CITY MD
NOV 27

The Columbia Amateur Radio Association (CARA) will hold its CARA Hamfest on November 27, 1977, at the Ellicott City Armory in Ellicott City, Maryland. Program includes exhibits, flea market, prizes, and refreshments. All indoors. No tailgating. Talk-in on 147.99/39, 146.16/76, 146.52/52. For more info contact CARA, PO Box 850, Columbia MD 21044.

HAZEL PARK MI
DEC 4

The Hazel Park Amateur Radio Club is holding their 12th annual Swap & Shop on December 4, 1977, at the Hazel Park High School. Admission is $1.00 at the door. Main prize tickets are available from Robert Numerick WB8ZPN, 23737 Couzens, Hazel Park MI 48030. Reserve table space is available from WB8ZPN.

EDITORIAL BY WAYNE GREEN

MICROCOMPUTING: HOW'S IT DOING?

In addition to the uses of microcomputers in amateur radio, I looked upon this new field as an opportunity for radio amateurs to get into a new business which had the prospects of growing in an extraordinary way over the next few years. It seemed to me that amateurs were ideally suited to take advantage of this opportunity.

As a result of the large number of articles in *73* during 1975 and 1976, an estimated 25,000 amateurs have gotten interested in microcomputers and become involved with them. Quite a few of them have gone on to try for the golden ring through manufacturing or distributing microcomputers and peripherals.

Has the field grown as I predicted? For once my optimism was about equal to history instead of ahead of it and, yes, it has grown. By way of example, the first computer store opened in August, 1975. Not only is it still going, but by August, 1976, there were 50 computer stores around the country. By August, 1977, there were about 500 computer stores and no sign of any letup in growth. Have you heard of Nashua, New Hampshire? Well, there are two stores in that city, with a third getting ready to open!

What does it take to get into this business? If you go about it right . . . and I wrote a book on this subject a few years ago . . . you can start out with very little and build it quickly. You can also start out with a lot (as an investment) and let a managing firm hire the experienced people for you . . . and there already is such a firm in the business. Figure on about $250,000 if you go the straight investment route.

Perhaps typical of the underfinanced system of starting a store is the experience of a chap who wrote me recently. He opened his computer store in a major city with less than $1000 in the bank. His sales the opening month were $51. The second month he sold $5,500 worth of equipment and books. The third month it was $14,000 in sales. $27,000 the fourth month, and $31,500 the fifth month. Sales were slowed down a bit due to slow deliveries from many manufacturers, plus a growing need for cash for expansion. By the sixth month, he was ready to open a second store in the area.

Growth is a little slower out in the boondocks, but it is still healthy and very forgiving. More and more stories are coming in from readers of *Kilobaud* who have walked into one computer store after another with a big roll of money in their pocket with the intent of buying a computer system . . . only to be turned away by the utter neglect of the "salespeople." The fact is that few stores are run by people experienced in marketing and sales . . . as yet.

How has it been for people entering the manufacturing part of the business? Probably not untypical is the firm run by two young chaps I know. They got interested in microcomputers a couple years ago, but didn't have the money to shell out for an Altair system . . . so they built and programmed their own. I visited them in early August, 1976, and they had a working system which they had put together in a workshop in one corner of the garage. It looked good to me and I suggested that they show it at the next computerfest.

Dealers liked it at the show and placed orders . . . and they are going strong today. Not bad for a couple of 20-year-olds. Their system really had the crowds gathered around at Computermania . . . and every one of the television news teams made sure to include it on their coverage of the show.

Another youngster is 16-year-old Jeff of Jefftronics. He sells parts and small circuits. You'll see him at just about every computerfest in the country with his booth.

THE MARKET IS CHANGING

Microcomputing is a lot more complicated a hobby than amateur radio, so it is limited in its appeal. An awful lot of people won't spend the time and effort necessary to tackle this hobby. The result of this has been the inevitable dropping off of beginners in computing. There are a lot of new hobbyists, but not the flood that came into the hobby last year . . . a good part of which were radio amateurs responding to the articles in *73*.

This drop in hobbyists has, as I predicted, been taken up by the increasing interest of businessmen in microcomputers as ways to save money for their firms. Few computer stores now report less than 50% of their business going this route and many are experiencing up to 90% business sales. The hangup on earlier sales to business was the lack of suitable programs and dependable equipment. Now that these obstacles are being overcome, the increase in sales to this market should overshadow the hobby market completely.

There is still a big need for more equipment and more programs. My prediction is that we will see programs being sold in large numbers . . . perhaps about the way phonograph records and books are sold today. After all, once you have a computer, you can use it for business, for games, to write music, to generate creative art, to study any subject ever known to man, etc. There are hundreds of thousands of programs needed. I think we will see sales volumes on the order of $75 million per day just in programs within the next ten years . . . and I may be very low with that figure.

THE PIRATES ARE COMING! THE PIRATES ARE COMING!

While I've had a few beefs about CBers — in particular the HFer branch of the CBers — getting adventurous and coming into the ham bands, these have all been verbal reports — no one has written as yet about it. I'll take the problem a little more seriously when I have a few written reports on the situation in my hand.

But let's say that it is bound to happen, so what can we do about it? What have you done or would you do if you came up against a bootlegger on the air? It isn't that tough on two meters, where repeater groups have organized their act fairly well and are generally able to talk the bootlegger into getting together for coffee, only to have him met by The Fuzz. This has helped many a ham get back his stolen two meter rig.

On ten meters, you can easily tell if the chap is coming in via ground wave or skip. If he's local, it is time to hook up a loop and start hunting, helped by some other local hams. A personal visit by as many of your club members as you can round up — maybe 50? — will create an impression that should get through to all but the most hardened cases. A mass of people can be intimidating, even without any direct threats of violence.

What about reporting the miscreant to the FCC? Sure, complete with tape recordings, but don't expect much . . . if anything. The fact is that most of the responsibility for preserving our bands is in our hands. If we act to keep bootleggers out, we may succeed. We've seen how powerless the FCC is to keep some 100,000 or so HFers out of a band, even though they have a list of most of the people involved.

If you or your club has had any success with discouraging bootleggers,

Continued on page 183

LETTERS

NEVER SATISFIED

Two FCC policies, both in contradiction to FCC rules, have led to a gross inequity in the reassignment of two-letter W and K callsigns. Rule section 97.53 (j) states that, "Callsigns which have been unassigned for more than one year are normally available for reassignment."

An existing Commission policy does not conform to the spirit or to the letter of that rule. The contradictory policy came to light when an amateur requesting a specific two-letter callsign previously held by a silent key received a "no action" response from the Commission. The following is an excerpt from a letter written by Charles A. Higginbotham, Chief, Safety and Special Radio Services Bureau, to the amateur's congressman. The specific callsign involved has been deleted as the action is currently being reviewed by the FCC. In that letter, Mr. Higginbotham stated, "Although the amateur station license with callsign K- - - did expire on December 15, 1975, Commission procedure is such that callsign K- - - will not be purged from Commission records, and thus be available for reassignment, until some time in the future. We purge our records at irregular intervals. For this reason, we are unable to predict when callsign K- - - will become available." That letter was written in July, 1977, a full eighteen months after the callsign holder's license expired.

That policy, in and of itself, would not be so bad except for another Commission policy. That policy, as set forth in Mr. Higginbotham's letter, is that "... we do not 'hold' applications in anticipation of the availability of callsigns."

That second policy results in the following scenario: An eligible amateur desires a specific two-letter callsign; he researches the status of the callsign and finds that the prior holder is deceased or has let his license expire and a period of twelve months has elapsed; the amateur immediately makes application for the specific two-letter callsign; the Commission, upon receiving the application, returns it with a "no action" letter because the callsign has not yet been "purged" for reassignment. We all know how long it takes from the time an application is sent off until the time a response is received. In the interim, a less diligent amateur puts in a request for the same callsign. By chance, the callsign is "purged" the day before the second amateur's application is reached. An inequity has resulted.

The result of such Commission policies is that amateurs requesting specific two-letter callsigns enter into a game of Russian roulette with the Commission. The object of the game is to guess the date the Commission records will be "purged" and to time one's application for a specific callsign so that it will be received immediately after the purge.

One of these two arbitrary Commission policies must be changed in order to result in the equitable assignment of specific two-letter callsigns. If the Commission's policy with respect to the purging of its records is changed, applicants will know precisely when specific callsigns will become available for assignment. On the other hand, if applications are held until specific callsigns become available, applicants will know that if their application for a specific callsign is received prior to another application, they will be assigned such specific callsign when it becomes available.

Concerned amateurs are urged to write the FCC and demand that these policies be changed so that fairness exists with respect to the assignment of specific two-letter callsigns.

Los Angeles CA

TOUGH ONE

Many thanks for printing my letter asking for someone to monitor the Novice exam. I was able to contact a helpful ham and I was successful on my first attempt.

I might add that the exam was one of the hardest I have taken dealing with communications. Many of the questions do not appear in any of the guides I bought.

F. Cuillo WA2RQA
Wassaic NY

UNCHARACTERISTIC

I was moved very near to anger and rage (very uncharacteristic) by the letter of one M. P. Lewton appearing in the August issue, favoring the loss of part of the 220-225 MHz amateur band to the citizen's service. After several days, I have calmed sufficiently to write this letter briefly stating my objections to Mr. Lewton and his three points, as follows:

1. His statement that "we amateurs ... could operate on the lost frequencies with our CB license" falsely assumes that I either have such a license now, or would ever stoop so low.

2. To say that giving up any amateur frequency would be compensated for by the availability of cheap radios seems to imply that amateurs cannot now use those frequencies, but will wait for the cast-off and surplus of a citizen's band instead of building or buying equipment intended for amateur service. That would be a sad commentary on the technical and financial state of radio amateurs if it were true. Nobody's making any more frequency spectrum, and to trade this precious resource for a few cheap CB sets that could be converted would be a bad deal for amateurs.

3. My answer to "CB really needs more room ..." is to look at what they are doing with the frequencies they now have. I am deeply embarrassed to think that people all over the world with shortwave receivers can tune across 11 meters during an opening and form their opinion of American mentality and demeanor from what they must hear from CB operators. If I had the power, I would move all CB operation to a single channel at 10 kilohertz, where they could share the frequency on a non-exclusive basis with Project Sanguine!

Jerold R. Johnson WA5RON
Austin TX

WATCH YOUR STEP

The 5th Signal Command in Worms, Germany, reports that the German federal postal and telecommunications department is to begin a "crackdown" on illegal CB operation by Americans in West Germany.

Some of the requirements for CB (low power radiotelephone) operation are: 2 Watts input, 500 milliwatts output to the antenna, omnidirectional antenna only; operation on channels 4 to 15 only; no connections to the public telephone system; and you cannot use a mobile as a base. Fees are DM 5 ($2.25) a month for mobiles, and DM 15 ($7.75) for a base. These must be paid on each unit. Absolutely forbidden are: beam antennas, linear amplifiers, and operation outside the federal republic of Germany. Also, you can't use your ears on the transport routes to and from West Berlin.

Travis Wade, vice-president of the Frankfurt area CB club, reports that most Americans in that area are so afraid of getting a "midnight knock" at the door by a German postal official that many of these people have gone QRT until they think that they can operate their illegal rigs again. It should be noted here that the German Polizei and the American MPs do not hesitate to call up the American CBers when there is an emergency or a lost child, etc.

American hams here in Germany would be well advised to carry a copy of their license in their car at all times, and to remove their equipment when their dependents are using their vehicles.

One good thing about operating in Germany is that you have a great deal of security about having mobile 2 meter gear. The penalties for auto break-in are severe and swift. So is the fine for illegal CB operation, sometimes as high as DM 3,000 ($1,300) plus imprisonment.

ACTION

I finally am getting off my rear to write. I have been faithfully reading *73* since I gave up my membership (and sub) to another organization. I think you are publishing the best ham radio magazine on the market

Now, a proposal, strictly food for thought How about a new, completely independent amateur radio league (call it what you like) — an organization that would represent its membership and not just use their money, an organization that thinks more of its duties to its members for WARC rather than a new building, an organization that listens to its members and answers their letters. I could go on and on, but I think you have the idea. Can you imagine a headquarters in New Hampshire? Unheard of! How about some response from *73* readers on this?

Keep up the objectivity of your magazine. A little controversy is great and helps keep the air cleared. Keep up the good work and best of luck.

Chuck Coffee WA6FLV
Rota, Spain

ANTI-RY

I just received my September issue of *73* and am sorry to say I don't like it at all; it is all one-sided for RTTY. I have nothing against RTTY, but a whole issue of it is too much.

I have noticed in the past few months that you are specializing on one field in each issue. I hope that this is not going to be your practice. I think the magazine will be a total loss or a bore to other readers who are not interested in that field.

One more thing I would like to see in your magazine is an article on amplifiers, especially on 15 and 10 meters! They are bad enough on 20m; let's hope they keep it there. I want everybody to enjoy ham radio, not just the ones with high power.

Donald Laroche WA2FXQ
Syracuse NY

HOT STUFF

I just wanted to send off my kudos to Mark Clark WB4CSK for his letter (Sept. 1977). I used to be a CBer, but I learned and studied and worked at the darn thing until I finally started getting regular correspondence from Uncle Charlie (in the form of upgraded licenses!) almost regularly.

I'm 14 years old (I got my Novice and Tech while I was 13) and first got my Novice and Tech back in the fall

Executive Editor

SPECIAL ISSUES

This issue of *73* is dedicated to OSCAR users, present and future. As you probably know, the newest amateur satellite launching is planned for the first of the year – details are in this issue. This bird will feature a UHF downlink for the first time, in the international amateur satellite band, no less! Many existing Mode B stations will be able to use their equipment with no problems. Hopefully, the new AMSAT entry will promote interest in UHF receiver design and techniques!

Even if you are not interested in satellites, the antenna and equipment referenced in the OSCAR articles can be used for standard VHF/UHF communications – who knows, the antenna you've been looking for might be described in an OSCAR article.

I have had several complaints about the special interest *73* issues this summer. Okay, I agree, not everyone is interested in RTTY and OSCAR. However, the content of the articles is applicable to all aspects of amateur communication. Please don't close your mind to new technology – satellites are becoming more and more commonplace in the amateur community; future AMSAT shots are going to provide hemisphere repeater operations – think about it!

At any rate, there are no more special issues in the mill right now. All suggestions for the same are appreciated!

THE COVER

The cover shot on this issue of *73* is an artist's rendition of the new bird – it really has not been launched yet! Credit to R. Michael Smithwick WA6TUF for the cover.

TAKE COVER

An article slipped into the RTTY issue last month that needed an editor's comment. The article, "RTTY Local Loop," is not really perfect for beginners. An isolation transformer is definitely required to isolate the loop from the power line! Otherwise, a shock could result from contact with the loop jacks if the plug is incorrectly polarized. In order to be safe, the isolation transformer should be inserted between the bridge and the power line. Be careful!

AN APOLOGY

Due to the extra demands placed on the *73* staff by Wayne's Computermania show, I have fallen behind in processing new manuscripts. I am currently about two weeks behind – take heart, your manuscript is not lost. As this is our deadline week, I will make a super effort to read all manuscripts by next week. Expect to have heard from me by the time you read this.

NEW TRENDS

Let me know what you think about the Gunnplexers and microwave information. If the general readership is not especially interested in new things, I will cease – however, until then, prepare yourselves! The experiments with the Gunnplexers are continuing; hopefully, in a month I will be able to write about the Doppler radar system I'm developing. This system is based on a counter with a modified timebase that will allow direct readout of range, speed, or whatever. Again, Computermania cut deeply into my free time!

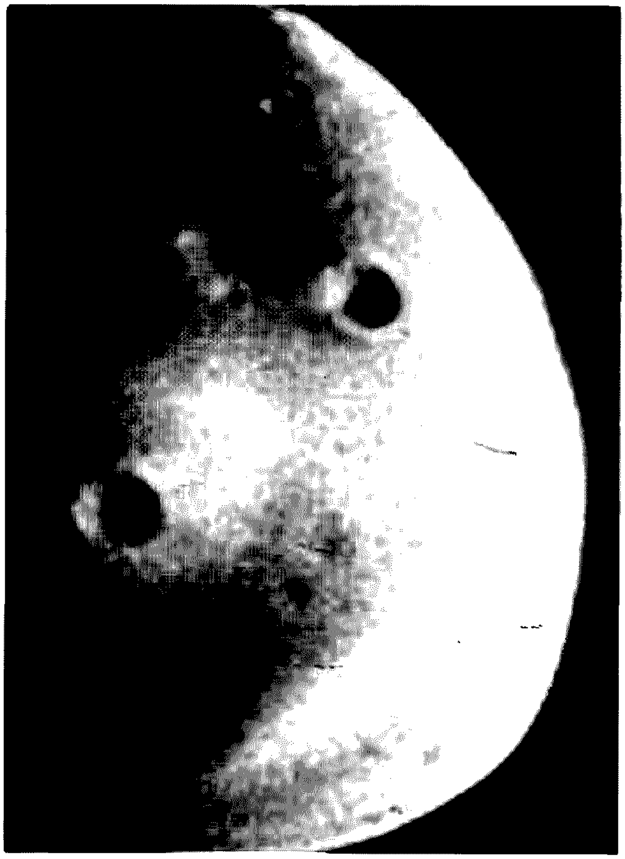
I obtained a Hughes neon-helium laser tube the other day, and am attempting to integrate it into some kind of experimental communications system. So far, a power supply using an automotive ignition coil is under construction. By the way, ignition coils are a good source (cheap) for high voltage at low current. A 24-volt transformer and variac can be used to drive the coil, which is nothing more than an autotransformer. It was very easy to obtain the 1200 volts required to fire my laser using such a scheme.

My wife is beginning to wonder what's up at our home – between the microwaves and now the laser, she's thinking about building a copper screen around the living area. Be careful when playing with these devices!

DEIMOS

So, you think SSTV is only good for transferring QSL cards and pix of the shack? This picture is courtesy of *73* associate editor Dave Ingram K4TWJ. Dave obtained the picture from the "N6V" gang at the Jet Propulsion Laboratory. This picture is computer processed, and formerly unreleased. Dave has been doing considerable work in slow and fast scan television with JPL – so without additional comment, I'll let the Viking News Center (Pasadena CA) tell the story:

"This is a computer-generated color picture of Deimos, smaller of the two satellites of Mars. A pair of images of Deimos from Viking Orbiter 1 – one taken through the camera's violet filter, the other through the orange filter – were combined in this single image to search for color differences on the surface of Deimos. Resolution in this picture shows objects as small as 200 meters. Deimos is a uniform gray color; slight tints of orange on the rims of some craters are artifacts of the image process. A small blur beside the large crater at the right is where scientists removed a reseau mark from the original image. The reseau marks etched on the imaging system are used to make precise measurements of the objects in the photos."



CONTESTS

Editor:
Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

Information on all 1978 contests should be forwarded as soon as possible *directly to me* for publication. Help avoid multiple contests on the same weekend with conflicting schedules by having your dates published as early as possible. Also, don't forget to send abbreviated results and any award information.

For a slight twist this year, take a listen during the OK DX contest. Last year there was good activity from Europe even though it was on the same weekend as Sweepstakes.

Anyone interested in a fine newsletter for contesters should check the *National Contest Journal*, published bi-monthly by the Southern California Contest Club, edited by Pete Grillo N6CJ. Subscription rates are $4/year in USA, $5/year elsewhere. For more information write: NCJ, PO Box 3762, Glendale CA 91201.

ARRL SWEEPSTAKES

CW
Starts: 2100 GMT Saturday, November 5
Ends: 0300 GMT Sunday, November 6
Phone
Starts: 2100 GMT Saturday, November 19
Ends: 0300 GMT Sunday, November 20

Sweepstakes is sponsored by the ARRL and is open to all amateurs in the US, US possessions, and Canada. No more than 24 hours of operation are permitted during the 30-hour contest period. Time spent listening counts as operating time and off periods may not be less than 15 minutes. Times on and off as well as QSO times must be entered in the log. Each station may be worked only once, regardless of band.

CLASSES:

All entries will be classified as either single or multiple operator stations. Single operator stations will be further classified by input power: Class A = 200 Watts dc or less, Class B = above 200 Watts. All ARRL affiliated clubs may also participate in the club competition.

EXCHANGE:

Number, precedence, your call, CK, and ARRL section. Send A for precedence if power is 200 Watts dc or less, otherwise send B. For CK, send the last 2 digits of the year you were first licensed.

SCORING:

Score 2 points for each completed QSO. Final score is sum of QSO points multiplied by the total number of ARRL sections plus VE8 (max. 75).

AWARDS:

Certificates will be awarded to the highest scoring Class A entry and the highest scoring Class B entry in each section, provided there are at least 3 single operator entries or the score is 10,000 points or more. Certificates will also be awarded for high scoring Novices and Technicians. Multi-operator entries are not eligible for certificate awards and will be listed separately in the results.

FORMS:

It is suggested that contest forms be obtained from ARRL, 225 Main St., Newington CT 06111. All entries with 200 or more QSOs must have a cross-check sheet to check for duplicate QSOs. Each log must show date, QSO time, times on/off, exchanges sent and received, band and mode.

Note: These rules were taken from last year's contest.

RSGB 7 MHz DX CONTEST

Phone
Starts: 1800 GMT Saturday, November 5
Ends: 1800 GMT Sunday, November 6

EXCHANGE:

Report and serial number, starting with 001.

SCORING:

Non-British Isles stations score 5 points for each contact with the British Isles; those outside Europe score 50 points. All may claim a bonus of 20 points for each British Isles numerical prefix worked (G, GC, GD, GI, GM, GW — 2, 3, 4, 5, 6). Contacts with stations using GB prefixes will not count for bonus points.

AWARDS:

Non-European stations must make at least 10 QSOs to qualify for an award.

LOGS:

Logs and entries must be addressed to the HF Contests Committee, c/o J. Bazley G3HCT, Brooklands, Ullenhall, Solihull, West Midlands, England, to arrive no later than December 29.

MISSOURI QSO PARTY

Starts: 1800 GMT Saturday, November 12
Ends: 2300 GMT Sunday, November 13

The 13th annual QSO party is sponsored by the St. Louis Amateur Radio Club in an effort to activate some of the hard-to-get Missouri counties. The same station may be worked once per band and mode. Missouri mobiles will count separately from each different county.

EXCHANGE:

QSO Number, RS(T), and QTH; county for MO stations; state, province, or country for others. MO mobiles start with #1 from each county activated.

FREQUENCIES:

3540, 3910, 7040, 7240, 14040, 14270, 21110, 21360, 28110, 28600, 50-50.5.

SCORING:

Score 1 point per QSO; MO stations multiply contact points times number of states, provinces, and countries; others multiply by number of MO counties (115 max). MO mobiles total separate score from each county activated.

AWARDS:

Certificates to top scores in each state, province, country, top 10 MO entries, and top 3 MO mobiles.

ENTRIES:

Mailing deadline for logs is December 15. Address all entries to: St. Louis ARC — KØLIR, 842 Tuxedo Blvd., Webster Groves MO 63119. Include an SASE for results.

DELAWARE QSO PARTY

Saturday, November 12
0001 to 0600 and
1600 to 2200 GMT
Sunday, November 13
0001 to 0600 and
1600 to 2200 GMT

Sponsored by the Delaware ARC, contest is open to all amateurs. Stations may be worked once per band/mode for QSO points.

EXCHANGE:

QSO number, RS(T), and QTH — county for DEL, ARRL section or country for others.

SCORING:

DEL stations score one point per QSO and multiply total by number of ARRL sections and countries worked. Others score 5 points per DEL QSO and multiply by 1 if one DEL county is worked, 3 if two counties worked, and 5 if all three counties worked (counties = Kent, New Castle, and Sussex).

FREQUENCIES:

CW - 3560, 7060, 14060, 21060, 28160.

Phone — 3975, 7275, 14325, 21425, 28650.

Novice — 3710, 7120, 21120, 28160.

ENTRIES AND AWARDS:

Appropriate awards given top scorers and a special certificate to all stations working all three Delaware counties. Mailing deadline is Dec. 31 to John R. Low K3YHR, 11 Scottfield Drive, Newark DE 19713. Include an SASE for results or W-DEL certificate.

EUROPEAN DX CONTEST

RTTY
Starts: 0000 GMT Saturday, November 12
Ends: 2400 GMT Sunday, November 13

Rules for the contest are the same as for the Phone section, with one exception: In the RTTY section, contacts with one's own continent are permitted and count 1 point per QSO. Multipliers will be counted as before.

Complete rules appeared in the August issue on page 22. Briefly, the basic rules are as follows:

Use all bands 3.5 through 28 MHz, with only 36 hours of operation out of the 48-hour contest period for single operator stations. The 12-hour rest period may be taken in up to 3 periods. Classes include single operator (all band), and multi-operator with single transmitter.

EXCHANGE:

RST and progressive QSO number starting with 001.

SCORING:

Each QSO will count 1 point. A station may be worked once per band. Each QTC (given or received) counts 1 point — see August issue. The multiplier for non-European stations is the number of European countries worked on each band. Europeans will use the ARRL countries list. In addition, each call area in the following countries will be considered a multiplier: JA, PY, VE, VO, VK, W/K, ZL, ZS, UA9/UAØ. The multiplier on 3.5 MHz may be multiplied by 4; the multiplier on 7 MHz may be multiplied by 3; the multiplier on

CALENDAR

Nov 3-4	YLRL Anniversary Phone Party
Nov 5-6	ARRL Sweepstakes — CW
Nov 5-6	RSGB 7 MHz CW Contest
Nov 12-13	IPA Contest
Nov 12-13	European DX Contest — RTTY
Nov 12-13	Missouri QSO Party
Nov 12-13	Delaware QSO Party
Nov 13	OK DX Contest
Nov 19-20	ARRL Sweepstakes — Phone
Nov 19-20	WWDXA International CW Contest
Nov 19-20	All Austrian Contest
Nov 26	Ten Meter Ground Wave Contest
Nov 26-27*	CQ WW DX CW Contest
Dec 3-4	ARRL 160 Meter Contest
Dec 10-11	ARRL 10 Meter Contest
Dec 17-18	CW Christmas Party

*Described in last issue.

14/21/28 MHz may be multiplied by 2. The final score is the total QSO points plus QTC points, multiplied by the sum total multipliers from all bands.

AWARDS:

Certificates to highest scorer in each country, reasonable score provided. Continental leaders will be honored. Certificates will also be given to stations with at least half the score of the continental leader.

LOGS:

Use a separate log sheet for each band. Logs for the RTTY section should be mailed no later than December 1. North American stations may send their contest logs to: H. E. Weiss WA3KWD, 762 Church St., Millersburg PA 17061, USA. All others should send their logs to: WAEDC – Committee, D-895 Kaufbeuren, Postbox 262, Germany.

IPA CONTEST

Saturday, November 12
0800 to 1000 and
1400 to 1700 GMT
Sunday, November 13
0800 to 1000 and
1400 to 1700 GMT

Sponsored by the International Police Association Radio Club – German Section (IPARC), the contest is designed to enable participators to work the Sherlock Holmes Award (SHA). The contest is open to all radio amateurs and SWLs. Members may work anyone, non-members may only work members. General call is "CQ IPA." Cross-band and cross-mode contacts are not allowed. All contacts must be on CW or SSB.

EXCHANGE:

Non-members send RS(T) and serial number. Members send IPA, RS(T), and serial number.

SCORING:

Every completed QSO counts 2 points on 80/40 meters, 4 points on 20/15/10 meters. Stations may be worked once per band. Multiplier is number of DXCC countries; every band counts separately. Final score is QSO points times multiplier.

FREQUENCIES (as allowed):

SSB – 3650, 7075, 14295, 21295, 28650.

CW – 3575, 7025, 14075, 21075, 28075.

AWARDS AND ENTRIES:

Certificates to winners and three highest scores. Any amateur fulfilling the conditions of the SHA50, SHA100, or SHA200 during the contest may apply with application sheet. Approval of 2 licensed hams is not necessary for contest application. SHA rules, IPARC membership list, SHA application sheet, contest log sheet, and contest score or certificates are available from Vince Gambina WB4QJO, 7606 Kingsbury Road, Alexandria VA 22310 – include an SASE, please! Contest entries must be postmarked no later than December 31 and sent to Adolf Vogel DL3SZ, Ritter-von-Eyb-Strasse 2, D-8800 Ansbach, Germany.

INTERNATIONAL OK DX CONTEST

Contest Period:
0000 to 2400 GMT
Sunday, November 13

The participating stations work stations of other countries according to the official DXCC Countries List. Contacts between stations of the same country count only as a multiplier, but 0 points. All bands from 160 to 10 meters, CW and phone may be used. (OK stations are only licensed to operate CW on 160 meters.) Cross-band as well as cross-mode contacts are not valid.

EXCHANGE:

Exchanges consist of a 4 or 5 digit number indicating the RS(T) and ITU zone.

SCORING:

A station may be worked once only on each band. A complete exchange of codes counts one point, but three points for a complete contact with a Czechoslovak station (except as noted above for stations in the same country). The multiplier is the sum of the ITU zones from all bands. Final score is then the sum total of contact points times the multiplier.

CATEGORIES:

A – single operator, all bands; B – single operator, one band; C – multi-operator, all bands. Any station operated by a single person obtaining assistance, such as in keeping the log, monitoring other bands, tuning the transmitter, etc., is considered as a multi-operator station. Club stations may work in category C only.

AWARDS:

A performance list of participants will be worked out by the contest committee for each country. A certificate will be awarded to the top scoring operators in each country and each category. The "100 OK" award may be issued to stations for contacts with 100 Czechoslovak stations, and the "S6S" award (and/or endorsements for individual bands) may be issued to a station for the contacts with all continents. Both awards will be issued upon a written application in the log. No QSL cards are required for either award.

LOGS:

A separate log must be kept for each band, and must contain date and time in GMT, station worked, exchange sent and received, points (0, 1 or 3), and ITU zone (with the first QSO for that zone only). The log must contain in its heading the category of the station (A, B, or C), name and callsign, address, and band or bands. Also, indicate the sum of contacts, QSO points, multipliers, and the total score of the participating station. Each log must be accompanied by the following declaration:

I hereby state that my station was operated in accordance with the rules of the contest as well as all regulations established for amateur radio in my country, and that my report is correct and true to the best of my belief.

Logs must be sent to The Central Radio Club, Post Box 69, Prague 1, Czechoslovakia – postmarked no later than December 31, 1977. A list and map of ITU zones is available for 2 IRCs from the same address.

WWDXA INTERNATIONAL CW CONTEST

Starts: **0000 GMT Saturday,**
November 19
Ends: **2400 GMT Sunday,**
November 20

Sponsored by the Worldwide DX Association and *DXers Magazine*, the objective is to contact as many amateurs in as many ITU zones and countries as possible using all available frequencies. All assigned amateur radio frequencies from 0.1 MHz to 25 GHz including transponders and repeaters of amateur satellites may be used. There are no contest limits; you may use complete automation devices, including tape recorders, auto keyers, readout devices, or other automatic CW devices. You must, however, follow the rules and regulations governing amateur radio in your country. Multi-operator, multi-transmitter entrants are encouraged. Single operator, single transmitter, single band entrants must state single category for special recognition. All entrants are assumed to be multi/multi/multi unless otherwise stated. The purpose is to encourage group contesting to enhance teamwork and interaction. Shortwave listener entries are a separate category.

EXCHANGE:

All stations must exchange reports and ITU zone numbers. Mobiles changing zones during the contest period will make changes in report sent to show the new zone. Shortwave listener logs must reflect zone numbers.

SCORING:

3 points for contact on different continent, 1 point for contact of different country but same continent, 10 points for contact by satellite transponders or repeaters, 0 points for your country contact, but multipliers count. Multipliers are each ITU zone contacted per band and each country contacted per band. Final score is total QSO points times total multiplier. SWLs score same but on heard basis. Land and sea mobiles count as different continent (3 points).

ENTRIES AND AWARDS:

Submit your contest summary sheet to the contest committee. *Do not submit your logs* – only the summary sheet. Include name and callsigns of all operators and listeners. Contest committee reserves the right to request your log to verify your entry in the event of close or tie scores. Summary sheet must be postmarked before January 1; contest synopsis will be mailed to each entrant before February 15. Trophies, prizes, or negotiables are solicited for award within country of origin. Results of the contest committee are final. Mail entries to: Frank Jerome W5AT, 908 Holoway, Midwest City OK 73110.

ALL AUSTRIAN CONTEST

Starts: 1900 GMT
November 19
Ends: 0600 GMT
November 20

The contest is open to all amateurs; power input must be in accordance with licensing regulations. All contacts must be on 160 meters, on CW only. Foreign stations use the call "CQ OE," Austrian stations will use the call "CQ TEST." The authorized suballocations for Austria are: 1.823-1.838, 1.854-1.873, 1.873-1.900 MHz.

EXCHANGE:

RST and QSO number starting with 001. Each exchange must be confirmed by repeating the exchange code.

SCORING:

Every completely logged QSO (date, time in GMT, frequency in MHz, call of station, exchanges given and received) counts one point. Multipliers are 2 points for every Austrian "Bundesland" (OE 1-9), and one point for every prefix. Multiply QSO points times multipliers for final score. Every station can be contacted only once. If a station is contacted twice, the second QSO must be clearly marked as a duplicate and does not count.

ENTRIES:

Logs must be postmarked no later than December 15 and sent to: Landesverband Salzburg des OVSV, "AOEC 1977," c/o Ing. Wolfgang Latzenhofer OE2LOL, Pfeifferhofstrabe 7, A-5020 Salzburg, Austria.

TEN METER GROUND WAVE CONTEST

November 26
9 pm to 1 am Local time

Sponsored by the Breeze Shooters of Pennsylvania, send an SASE to Richard Evanuik WA3LUM, 311 Evergreen Ave., Pittsburgh PA 15209, for logs and new rules. There will be separate categories for Novice/Technician classes.

AMSAT

AMSAT-OSCAR 7 ORBITAL DATA CALENDAR

In cooperation with AMSAT, Skip Reymann W6PAJ has published an improved AMSAT-OSCAR orbital data calendar containing all orbits for 1978 for AMSAT-OSCAR 7. Designed so that it may be hung on the wall, the calendar includes information on the operating schedules and frequencies for the spacecraft, and also the telemetry decoding equations. Also included is step-by-step information on how to determine times of passage of the satellite.

The orbital calendar is available postpaid for $5.00 U.S. funds or 30 IRCs ($3.00 to AMSAT members, and free to AMSAT Life Members). Overseas orders will be airmailed. Orders and payments should be made in U.S. currency to: Skip Reymann W6PAJ, P.O. Box 374, San Dimas CA 91773.

Important – To speed up handling of your order, please include a gummed, self-addressed label.

Proceeds from the Orbital Calendar benefit AMSAT.

Looking West

Bill Pasternak WA6ITF
24854-C Newhall Ave.
Newhall CA 91321

Coordinators, coordination councils, and concerned spectrum users should take note of the following date: September 23, 1978. If plans jell as it now appears they will, on that date the Southern California Repeater Association, the San Diego Repeater Association, and the 220 Club of San Diego will cosponsor this nation's first *VHF/UHF National Voluntary Coordination and Band Planning Meeting* in the city of San Diego, California.

It has been obvious for a long time that coordinators and coordination councils all over the nation face similar problems and that some format has to be found to get all of these people under one roof for a day or so to give them a chance to talk over their ideas with one another. No individual or group had made any move toward setting up such a get-together. The initiating step took place at the August 20, 1977, SCRA General Membership Meeting held in La Jolla. In his remarks welcoming the SCRA to the La Jolla-San Diego area, Sam Deer suggested that the SCRA schedule its fall, 1978, meeting so that it could be held at the 1978 ARRL National Convention that he and his staff are putting together at this time. "Why not make it a national coordinators meeting instead?" suggested Bob Thornberg WB6JPI, and at that moment was born the idea of SCRA hosting the first meeting of this kind.

However, an event of this scope would necessitate support from as many amateurs as possible, and since this will be a seminar held in San Diego, it was felt that the amateur community of that city must be directly involved. Therefore, after some quick discussions and a few letters, it was decided that rather than have it be an SCRA-sponsored gathering, it would be cosponsored by the three organizations mentioned above.

Since plans are still in the formative stages, it's hard at this moment to describe any program for the meeting itself. One suggested plan is to hold two separate sessions, with technical issues discussed in the morning and matters of a political nature taken up after a good lunch. However, since it has been but two weeks since the idea itself was conceived, exact plans have yet to be formulated. In either case, it is hoped that this meeting will be attended by delegates from all voluntary coordination councils (and/or coordinators) here in the United States and worldwide, as well as individual amateurs who are truly concerned with overall VHF/UHF voluntary spectrum management.

Further information on this meeting will soon appear both here and in most other amateur publications. In the interim, if you think you might want to attend or wish to make reservations for a seat (the meeting is *free*, but the sponsors would like to know how many people to expect), drop a note to the attention of Mr. Paul McClure, Secretary, Southern California Repeater Association, PO Box 2606, Culver City CA 90230. Mark your envelope "Coordination Meeting Info Request," and please include an SASE. This meeting may mark a historic moment in amateur radio's future, so plan to attend.

CALL FOR PAPERS

SCRA Chairman Jim Hendershot has informed me that I have been "volunteered" by the SCRA to handle their involvement in the meeting. One idea that I have is to invite you who plan on attending to submit formal "papers" for consideration and/or presentation at the seminar next September. In this way, many divergent opinions and ideas could be expressed in a short time on such topics as "The Future of Voluntary Spectrum Management by Amateurs," "Coordination Methods for Relay Communication," "The Anatomy of a Voluntary Coordination Council," "User Involvement in Repeater Coordination," "Advanced Coordination Techniques Using Microprocessors," "Possible Voluntary Coordination of Non-Relay Spectrum Operations," etc. You need not limit yourself to the aforementioned list — use your imagination. Even if you oppose the concept of voluntary spectrum management and feel you have a good argument to prove your point, go ahead and submit a presentation. Since this seems to have been placed in my lap anyhow, it is my intention to get a "judging committee" put together that will be made up of the best technical minds I can muster. Those authors whose papers are selected will be invited to present them at the meeting.

I guess that at this point some "ground rules" might be in order. First, use whatever written format you like. It's content, not writing form, that's important. Second, it should be long enough to present your views in an easy-to-understand manner, yet not so overly long as to put everyone to sleep. One way to be sure is to read it into a tape recorder after you have finished it. If it runs no longer than, say, 15 minutes and holds your interest, then you have a potential winner. If, after listening for 45 minutes, you find yourself falling asleep, then I suspect that some text editing is in order.

Let's set a submission cutoff date of June 15, 1978. This will give the committee a chance to read and judge all submissions and notify those authors selected. However, once you find out that you are one of the chosen presenters, it's up to you to get to the meeting on your own. Neither the SCRA, SANDRA, or the 220 Club of San Diego will be responsible for providing transportation to the meeting, lodging, or any other expenses. Costs of such would be prohibitive. However, if you are one of the "dedicated" ones, you have already planned to attend both the ARRL National and this meeting, so dust off the typewriter and get going. Send all submissions to my attention, in care of the SCRA PO box in Culver City. Also, if you want your presentation returned should it not be chosen, please enclose an SASE.

PETE HOOVER ON USER INVOLVEMENT IN REPEATER COUNCILS

Herbert "Pete" Hoover III W6ZH is probably one of the most respected members of this nation's amateur community. On August 20, 1977, Pete addressed the membership of the SCRA on the topic of "User Involvement in Repeater Councils." Here is a partial text of Pete's talk:

"I've been involved in repeaters at one time or another, of one kind or another, since I got back from Europe in 1964. I had control station for one of them for a while, first AM and now FM. I'm not a stranger to the mode of communication; however, I am not as far aside as Stan Brokl is, who wrote the comment in here *(referring to an article that appeared in various local radio club newsletters)* saying that the two meter repeaters are very close to CB activity. I wish they were in some respects.

"A week ago, I was in Dallas talking to the REACT International Convention. They have a repeater on 460. I think they have a bunch of them. They do a good job with them. They're commercial users.

"I would much rather be stuck on the road and have to ask REACT for help than I would be stuck on the road and have to ask the average repeater user for help. You might as well just forget it. Why? Because repeater operators are primarily interested in themselves. They are interested in commercial communications suppliers like themselves *(referring to repeater owner operators)*. They are not user-oriented. Okay, fine, ATV is the same sort of thing, perhaps. But there is a problem in the southern California region — at least four people have mentioned it in different terms today: There are no more frequencies *(referring to available southern California two meter and 220 MHz channel pairs)* under the present situation.

"And not only that, the communications service suppliers, the people who provide communications services — which are you people primarily — repeater operators *(owners)* are becoming increasingly remote for the reason that you exist: your users. The comment was made here earlier today — Is it possible to include a user viewpoint in this kind of organization? I'm telling you, you'd better!

"You are, for all intents and purposes, a communications utility. Remember the words — they're going to be used more and more. Think back on the utilities that you normally think about when you hear the words. Power company, gas company, railroads, airlines, truckers. They abused the users of their services to the point where the federal government stepped in. And, ladies and gentlemen, if the repeater community does not get its act together, you are going to hear that as a suggestion

Pete Hoover W6ZH addresses the SCRA at La Jolla.

FCC Math

John F. Leahy WB6CKN
P.O. Box 539
Gonzales CA 93926

This is the first in a series for hams and would-be hams who have trouble with math. What we'll do over the months is take the equations and other math stuff you run into in FCC exams and handle them in a relaxed yet thorough fashion, so that when you go to face the friendly executioners down at the FCC office, you'll be well prepared to breeze through any math curves thrown at you.

So, if you are a person who can handle simple adding, subtracting, multiplying, and dividing okay, but tend to shrivel up into a quivering blob when faced with math that is more demanding, this series is for you!

First, let me assure you that if you fit into this category, you have plenty of company. Recent studies have shown that better than half the adults in the country can't add. Of course, people in electronics tend to be somewhat more capable along math lines than most, but if you're not a scientist, engineer, math buff, or something, chances are there are areas of math where you do not quite feel at home, to put it mildly.

Since the series will start with simple stuff and progress through all the math you could possibly need to pass any FCC exam (and just about anything you might run into in popular books and magazines, for that matter), you should be able to eliminate areas of difficulty with very little trouble, providing, of course, that you do what's necessary to let the series go to work on you. A good quiet nook (not the ham shack, unless you're good at resisting temptation), far removed from shrieking kids and a hysterical XYL, plentifully supplied with paper and writing materials, is usually helpful.

No doubt some of the math of this series will be second nature to you. There's no reason why you shouldn't skip such. A quick glance through each bite-sized part as it comes along should tell you if this is an area where you need some review or not. Since each part is pretty much self-contained, skipping certain sections or jumping back and forth should introduce few problems.

One urgent recommendation: If you are one of the vast multitude for whom math has been, is now, and, you fear, ever will be a major catastrophe, RELAX! I really mean relax. *The biggest single obstacle to mastery of anything is being uptight about it. If you can learn to relax away the fears, anxieties, and inner turmoil that have built up over the years, you will find that there is no area of math you cannot completely master, given the right approach and sufficient time.*

A good way to relax with math is to consider it a game. If you like checkers or chess or bridge, you can like math. It's just a matter of developing the right outlook. If you enjoy doodling or have ever spent time on picture or crossword puzzles, then you are indubitably a person who can enjoy, yes, take real pleasure in, math. And there is this consideration: Whereas in bridge or checkers or chess, someone has to lose the game if someone else wins, in math no one need lose. You might be delayed for a while, reviewing something you've forgotten, or distracted (that lithesome bikinied lass next door), but there's no losing unless you choose to lose. And you will find that solving a math problem in electronics is just as satisfying as winning a game of chess, if you let it be. In fact, as you progress along finding yourself more and more successful, you may very well become almost as hooked on math (yea, verily) as you are on amateur radio. But enough of this — let's quit talking and start building.

As I said earlier, we'll work primarily with the equations you might well find in an FCC exam. One of the first, which appears in various forms, is f = 300,000,000/wavelength. We'll dally a bit on this formula so as to develop some of the approaches we'll use throughout the series.

Another way you might see it written is $f = c/\lambda$, where c is the symbol ordinarily used for 300,000,000 meters per second, the velocity of light, and λ, the Greek letter lambda, is the symbol used by physicists, engineers, etc., for wavelength.

Before we go any further, let's see what different forms this formula can be wiggled into. To find out what kind of wiggling is legit in electronics math, we'll play around with some numbers. Take the equation $5 = 10/2$, which might be translated: 5 equals 10 divided by 2. [Any fraction can be considered a division. Divide the bottom (denominator) into the top (numerator)]. You'll notice that $5 \times 2 = 10$ and that $10/5 = 2$. Well, if math is universally valid (let's not get into philosophical questions here), then using our formula, $f = c/\lambda$, it must be true $f \times \lambda = c$ and that $c/f = \lambda$. (Remember that for purposes of math manipulation, letters can be handled just as though they were numbers.) So there are three basic configurations of the formula. Which of the three should be used in a particular case depends upon whether you are trying to find the frequency or the wavelength (presumably you'll never be solving for the velocity of light).

You may have heard, somewhere, that light (and other electromagnetic waves, including radio) travels 186,000 miles per second. Of course, scientists, in an effort towards uniformity and logic, use meters per second rather than miles per second. A meter, as you may know, is a lot shorter than a mile, in fact a *thousand* of them is still less than a mile. To be more or less precise, a meter is 39.37 inches, a little over a yard in length (a yard, you will recall, is 3 feet or 36 inches long). Now let's take that 186,000 miles and see if it comes out to the 300,000,000 meters of our formula. There are 5,280 feet in one mile, so there must be 5,280 x 186,000 = 982,080,000 feet in 186,000 miles. Anywhere along the line you're not quite sure of the reasoning, it might be a good idea to stop and play around with the ideas involved so as to get a clearer picture of why we do what we do. For example, why did I multiply 5,280 x 186,000 instead of, say, dividing? If you're not sure, then you want to picture the relative sizes of miles, yards, feet, inches, meters, etc., trying mentally to fit the smaller into the larger, asking yourself how many of the smaller fit inside one of the larger, drawing pictures representing their lengths (trying to draw to scale, if possible) and in general playing with drawings and mental pictures until it's crystal clear how we go about converting one unit of measurement into another. Now take that 982,080,000 feet, multiply by 12 (because there are 12" in one foot), and we have 11,784,960,000, the number of inches in 186,000 miles. Now all we have to do is divide that number, 11,784,960,000 inches, by 39.37, the number of inches in one meter, and we have 299,338,582. So 186,000 miles works out to 299,338,582 meters, quite close to the 300,000,000 of our formula. In fact, both 186,000 miles per second and 300,000,000 meters per second are approximations of the value for the speed of light. Approximations are all we need and, indeed, the best science can do.

A few comments are now in order. Notice the large numbers we were into above. Even with a calculator that can handle such numbers, errors are easily made. Electronics is full of computations with numbers larger than those we just experienced. Hence shorthand methods for handling such numbers had to be developed, and you will need to learn them if you have not already done so. We will cover such shorthands in future lessons.

That 300,000,000, then, is the fantastic distance in meters a radio wave travels in one second. What, you might ask, has that to do with frequency and wavelengths? (Our formula, remember, says that frequency equals 300,000,000 divided by wavelength.) As a matter of fact, everything follows logically from the meaning of the two words, frequency and wavelength. Frequency is the number of complete cycles of a particular signal that occur in one second. Wavelength is the distance a wave front travels, zipping along at the speed of light, during the time it takes the generator of that signal to produce one complete cycle.

If we take an example, we should be able to nail this all down. Supposing your CW transmitter's putting out a signal at 3.625 MHz. That's 3,625,000 cycles per second. M in MHz stands for mega, you may recall, and mega means million. With our decimal system the way it is, the 3 in that 3.625 is the millions and the 625 is therefore thousands.

Now we ask ourselves how long it would take for one cycle of that frequency to be produced. Obviously it would be a mighty short bit of time. Well, if there are 3,625,000 cycles in one second, then one cycle takes 1/3,625,000 of a second (just like if you travel at 60 miles per hour, one mile takes 1/60 of an hour, which just happens to be one minute). Again, play around with these ideas, taking different examples, etc., if everything is not crystal clear to you. Notice that number, 1/3,625,000. It is one over or divided by the frequency. So the time it takes for one cycle is simply *1 divided by the frequency* seconds (providing, of course, that you're dealing with a frequency expressed in cycles per second). This particular configuration, 1 divided by the frequency, is called the *period* of the signal. And physicists use the symbol ν, the Greek letter nu, in formulas, etc., when performing calculations that require the use of a signal's period.

Next we ask how far the wave front of our signal would travel in that short period, 1/3,625,000 sec., because whatever that distance is, it is the *wavelength* of our signal. You may recall distance equals speed times time. If I'm going 60 miles per hour, and do so for 3 hours, then I've traveled 3 x 60 or 180 miles all told. For our radio signal, we multiply speed (300,000,000 meters per second) times time or *period* (1/3,625,000 sec.) thusly: 300,000,000/1 x 1/3,625,000 = 300,000,000/3,625,000 which equals 300,000/3,625. If you're not quite sure how we got rid of those last 3 zeros at the *end* of each number, and you'll find that you get the same answer as you would if you simply dropped those last zeros, providing you drop the *same number* of zeros from top (dividend, numerator) and bottom (divisor, denominator). The principle is simple. You're just dividing some power of ten (we'll go into powers later on) by itself, and, as you probably realize, whenever you divide something by itself, the result (quotient) is 1, and 1 times anything is that same anything. So just by crossing out the same number of end zeros on top and bottom, you've carried out a division and gotten rid of a hidden 1!

Before we find what 300,000/3,625 equals, you might notice that 3625 is our original frequency, but as it would look expressed in kilohertz (kHz). In other words, 3.625 MHz equals 3625 kHz (equals 3,625,000 Hz or cycles per second). We'll get back to this in a later lesson, and show how to use our formula, f = 300,000,000/wavelength, with megahertz, kilohertz, or Hertz (as we are in this lesson) without converting the megahertz or kilohertz into Hertz.

New Products

OPTOELECTRONICS FC-50 FREQUENCY COUNTER IMPRESSIONS

Considering myself a confirmed UHF/VHF enthusiast, I was pleased to review a new frequency counter useful in the UHF spectrum. My present counter is a home brew 50 MHz job constructed on perfboard, with a prescaler that starts to gasp at 450 MHz. Thus, the new Optoelectronics FC-50 counter with 600 WT prescaler could not have come along at a better time!

Optoelectronics is best known for their clock kits and electronic components. I was surprised to discover that they also offer a quality counter, available in kit and pre-built form. The basic counter is the model FC-50, which will respond in the range of 10 Hz to about 65 MHz. I evaluated a factory-built model, although instructions for the kit builder were provided. The user instructions provided with the kit assume some knowledge of components and mounting techniques; even so, they are easy to follow, and are complemented with several pictorial diagrams.

The FC-50 requires five volts for operation; thus, it can be used in the field with battery power and a 309 regulator. The eight digit LED display features leading zero suppression, which means that only the significant digits of the frequency being monitored will be displayed. The suppressed display is controlled by a front panel toggle switch. The LED display features .4" digits for easy reading. In addition to the leading digit suppress switch, front panel controls consist of a power switch, gate time control, and a prescale switch to enable the optional 650 MHz prescaler. The gate time control is a two-position switch which allows either a one second or 1/10 second sample time. In effect, this allows the display to be updated on either of the time intervals. A BNC connector is provided for rf injection.

The FC-50 counter has a claimed accuracy of 1 ppm (±.0001%). Stability after 25 minutes is also 1 ppm. Input sensitivity to 50 MHz is 10 mV rms, and impedance is 1 megohm with a load of 20 pF. If the 600 WT prescaler is used, the input requirements increase to about 150 mV rms.

Using the counter is a snap! I plugged my unit in and allowed a warm-up period of 10 minutes. My rf probe consisted of a three-inch clip lead twisted into a turn coil. This coil was attached to a short piece of coax which terminated in a BNC connector. I had a 2m Wilson HT nearby, which provided an easy test. Presto . . . the HT provided an accurate count at distances up to five feet from the counter! It was an easy job to calibrate my HT . . . sure enough, several channels were off frequency. No wonder I couldn't hit one of the "local" machines!

The real test came with the 450 MHz HT. This rig provides only 500 mW of output, and was originally calibrated by the old "tweak until you access the machine" method. Amazing — the counter immediately indicated the frequency, and, as it turned out, I was close. Without wasting any time, I checked my entire UHF setup, using the simple coil pickup in all cases.

In my opinion, the Optoelectronics FC-50 counter and 650 MHz prescaler are hard to beat for the price. The eight digit display makes accurate UHF counting possible, and the accuracy is definitely OK for amateur use. Housed in a 6" x 6" x 3" plastic box, the counter is attractive and portable. The most amazing thing about the FC-50, however, is the price. The basic 65 MHz unit in kit form is available for $119.95, complete! Factory wired, the unit costs $165.95. The prescaler kit is available for $29.95, and mounts inside the FC-50 case. This option is controlled by the front panel prescale switch. Sockets are provided for all IC packages, and quality components are in evidence throughout the counter. *Optoelectronics, Inc., Box 219, Hollywood FL 33022.*

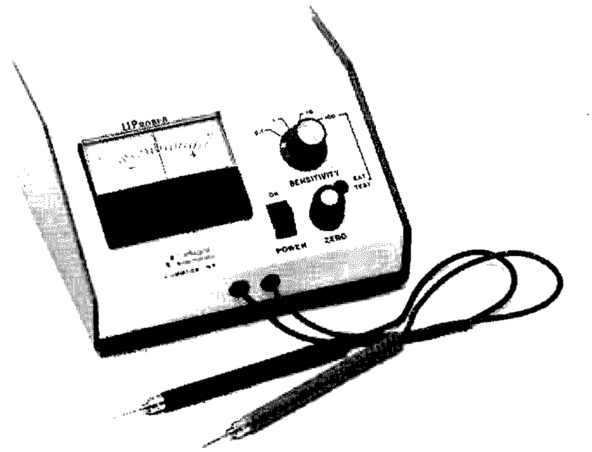
YAESU INTRODUCES THE MEMORIZER

A solid state, fully synthesized 800 channel 144-148 MHz two meter FM transceiver, Model FT-227R, featuring a photo optic sensor, has been announced by Yaesu Electronics Corporation of Paramount, California. This new Yaesu product has a memory circuit to put you on any preset channel with a flip of the memory switch, and has been designated the Yaesu "Memorizer."

Frequency readout is by means of four large LEDs. Optical sensing eliminates switch problems in frequency selection. PLL techniques are used for fully synthesized frequency control in 5 kHz steps, and a special memory circuit allows instant return to any preselected frequency within the two meter band. Plus or minus 600 kHz offsets, plus any odd split within the two meter band, can be achieved using the memory circuit.

The new FT-227R has automatic final protection, PLL unlock protection, and a busy channel indicator. It provides built-in tone burst, plus optional tone squelch-decoder, and selectable ten Watt or one Watt output. It exceeds the latest FCC requirements with spuries well below the minus 60 dB down requirement with superior cross modulation, overload, and image rejection. Compact (180 mm x 60 mm x 220 mm), lightweight (2.7 kg.), the FT-227R requires 800 mA on receive and 2.5 Amps on transmit at 13.8 V dc plus or minus ten percent. And, best of all, it is priced at under $300! The Yaesu FT-227R is scheduled for late September delivery to all authorized Yaesu dealers. *Yaesu Electronics Corporation, 15954 Downey Ave., P.O. Box 498, Paramount CA 90723, (213) 633-4007.*



Integral's Model 42 current tracing meter.

WIRE-WRAPPING WIRE

The finest industrial quality AWG 30 (0,25 mm) wire-wrapping wire is now available on compact, convenient 50' (15m) rolls. Perfect for small production applications, prototype jobs, or amateur electronics projects, the wire is silver-plated OFHC copper with Kynar insulation. This premium insulation combines excellent electrical and mechanical characteristics with easy stripability and is available in 4 colors (red, white, blue, and yellow), packaged on 1-5/8" (40 mm) diameter spools for easy handling and storage. Available for immediate delivery. *O.K. Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475.*

CURRENT TRACING METER INTRODUCED BY INTEGRAL ELECTRONICS CORPORATION

A current tracing meter, MICROPROBER Model 42, recently introduced by Integral Electronics Corporation, is specifically intended for isolating defective ICs on assembled printed circuit boards. The new instrument is especially useful in the troubleshooting of bus-oriented circuitry, such as encountered in microprocessor assemblies. Detection of random solder shorts on printed circuit boards and location of extraneous wires in back planes and wire-wrap assemblies are greatly simplified with the aid of this device. The sensitivity of the current tracer, spanning a 10,000:1 range, permits equally effective fault isolation of TTL, DTL, CMOS, and ECL circuits. The instrument is portable and powered by a single 9-volt battery, providing up to 300 hours of continuous operation.

Available from stock to 45 days at $94.50 each. For further information, contact Marcy Talbot, Sales Manager, *Integral Electronics Corporation, P.O. Box 286, Commack NY 11725, telephone (516) 269-9207.*

NEW TWO-WAY TEST SET INCLUDES COMPLIMENTARY CARRYING CASE

A Thruline® directional RF wattmeter and a Bird 100 W dry load constitute the core of the new model 4300-064 test set. Selected especially for convenience in servicing mobile communications equipment, accessories include an rf sampler with variable level control for signal frequency, spectrum and envelope analysis, two UHF connectors, two N connectors (on the Model 43 watt-

more and more often. And who from? Your users. And how many users are there versus how many suppliers? Repeater operators *(owners)*: You don't stand a chance.

"Okay, what's the answer? You can't do it by legislation. It has to be done in a voluntary manner. No two ways about it. You have to have an end objective, and your end objective must be to make better use of the one resource you have, the spectrum. You have to relate what you are doing to the users of your service. You have to ally yourselves as repeater operators *(owners)* with the organizations that your users belong to — Red Cross, Salvation Army, ARES, RACES. Sure, RACES is part of the repeater operators group. I can think of two RACES repeaters that in times of disasters turn themselves off!

"Suggestion (it's been made before, but please give it some serious thought): You've got some very competent people here. Consider, over a period of two years, phasing in something like the following, which is modeled primarily after the commercial FM broadcast practice. You have class A, B, and C stations, from very low power local machines (and this is akin to JR's comment about it being installed in someone's sub-basement, running a half a Watt to a wet noodle) to the 'clear channel stations' *(wide coverage)*, maybe like a .34/.94 on Mt. Wilson. Who knows? Chances are excellent that if you approach it from the same allocations viewpoint that the FCC has in the past used for allocation of FM frequencies (commercial ones for broadcast), you can increase the number of repeaters on the air by three- or fourfold without increasing your spectrum. But you are going to have to instill in your members a discipline that currently does not exist. It will have to be done by cooperation. This is probably going to require an alliance with users, and I am delighted to see someone from northern California here *(referring to NARC Chairman Dave Metts)*, 'cause that's where it begins.

"As a start, the only repeater that I am presently a user of is the ANY repeater in Pasadena. Talking to the people on that repeater, I understand that there is a potential conflict with AQD here in the Claremont area of San Diego. We are willing in Pasadena to reduce our ERP to 1 Watt. That will give us the possibility of covering the San Gabriel Valley and a portion of Los Angeles. We challenge AQD to do the same thing. This kind of thing, I think, will lead to a lot fewer headaches for your technical committees, and probably will give you a better system all around. That and aligning yourself with the Red Cross or any other communications user. Remember, you are only in business because your users let you stay in business. The moment they tire of you, there goes your toy. No longer can you put these things *(repeaters)* on the air for your own personal amusement — which is what most repeaters are on the air for, I'm sorry *(to say)*.

"That's the end of my general comments; I was delighted to see SCRA members at the L.A. Council of Radio Clubs meeting. To my knowledge, that's the first they had ever attended a meeting. I hope it occurs more often. Okay, enough of the lecture; any questions?"

This was transcribed directly from tape recordings made at the time and, with the exception of the deletion of his opening remarks pertaining to WARC '79, is presented totally unedited. Comments on the foregoing can be made either directly to Mr. Hoover or to him through this column.

THE BIG FIRE

By now, most of you are aware of the fact that this summer California suffered some of the worst wide-area fires in the state's history. They seemed to spring forth without warning to consume hundreds of thousands of acres of valuable land. In the case of the big Santa Barbara fire, hundreds were left homeless in the fire's wake.

I have received many reports of how amateur radio — both HF and VHF — has been working at the front lines to provide the necessary communication when called upon to do so. As I write this, the giant Marble Cone fire has just been "contained," and the weary firefighters are into their final "control" phase of the fight. It still will be many days before it's out.

Two people who have supplied information for us are Bob Couger W6KPS, who lives up near the Santa Maria area, and Bob Jensen W6VGQ, who was up in the fire area with a film crew. Their information, along with input derived from a report given to the SCRA by Southwestern Division Director John Griggs W6KW, make up the background for what you are about to read.

The most important aspect of amateur radio's involvement in the firefighting efforts was that amateurs arrived "ready to set up communications" — but were not pushy about it. They simply let those in charge of the overall effort know of their availability, and then waited to be asked to participate. They did not have to wait very long for the call. The fire being in the type of terrain it was, very little land-based communication already existed — and what there was in the

FCC Math

from page 21

Now back to that 300,000/3,625. Dividing out, we get 82.8, the length of one wavelength of our 3.625 MHz signal *in meters*. I leave to the reader the exercise of converting 82.8 meters to feet. Just remember there are 39.37 inches in a meter. The answer is below.* You may have noticed that I did not carry the division above out beyond one decimal point. The reason is simple. There's no reason to be more accurate than that here. You get a feel for proper degree of accuracy as you increasingly bump into reality.

Finally, let's tie everything together so we can see what we've done and where we've been. We started, you recall, with the formula f = 300,000,000/wavelength, which, with further symbolism, is $f = c/\lambda$. This can be tortured into the two variant forms: $f \times \lambda = c$ (or simply $f\lambda = c$; multiplication sign need not be written between two letters, and two letters next to each other are understood to be a multiplication) and $c/f = \lambda$. Then we took our elementary-school formula, distance = speed times time, and applied it to our case, getting wavelength = 300,000,000 times *period*. And since period is *1 over frequency*, we derived, really, the formula, wavelength = 300,000,000/f or $\lambda = c/f$, which, as you can see, is the second variant above, only written with the symbols interchanged from one side of the equal sign to the other (after all, it doesn't make much difference whether you say $2 + 2 = 4$ or $4 = 2 + 2$, does it?). So really, you don't need to remember the formula: frequency = 300,000,000/wavelength. All you need is distance equals speed times time, remembering that in our case distance is wavelength, speed is 300,000,000 meters per second, and time is *1 over frequency*. And if you can't remember what variants the formula can take, go back to a simple problem, e.g., $2 \times 3 = 6$, so $6/2 = 3$ and $6/3 = 2$, but notice that 6×3 does not equal 2, nor 6×2, 3, nor does $3 \div$ (divided by) $2 = 6$, etc. Only variations that work with numbers will work with letters. So, $fc \neq \lambda$ ($\neq$ means "does not equal"), $f/c \neq \lambda$, etc.

Now, with all this logic and all these tricks under your belt (if you'll pardon the mixed metaphor), here are a couple for you to work out. Check yourself against the answers (and work) below.

1. What is the free space wavelength of a 146.94 MHz signal (meters and feet)?
2. What is the frequency of a signal whose free space wavelength is 5 inches?

*271.7 feet. We multiply 82.8 by 39.37 to get 3259.8, the number of inches in 82.8 meters. Then divide by 12, getting our answer.

Answers

1. We use the formula $\lambda = c/f$. The 146.94 MHz is 146,940,000 cycles per second. So we have: 300,000,000/146,940,000 = 30,000/14,694 = 2.04 meters. Multiply 2.04 x 39.37 and we have 80.31 inches. Divide by 12 and we have 6.69 feet.
2. Here we are looking for frequency, so we use the formula $f = c/\lambda$. Our formula requires meters, remember, rather than inches. So we must first convert 5 inches into meters. Since there are 39.37 inches in one meter, we are here dealing with a lot less than one meter. In fact we are dealing with 5/39.37 of a meter. Divide that out and we have 0.127 meters. Slipping that into the formula, we have f = 300,000,000/0.127 = 2,362,204,000. Again, we need not carry the division all the way out. Just put in the correct number of zeros after working it out a reasonable amount, so as to get us into the right magnitude. 2,362,204,000 cycles per second is 2362.204 MHz, which is our answer. This matter of how far to work a problem out is not terribly important for our purposes, since FCC exams are multiple choice and once you have the first couple of digits and know the *size* of the answer (whether hundreds, millions, or whatever), you can easily select the correct answer.

Build the Omni-OSCAR!

-- practical omnidirectional antenna

Jay Buscemi K2OVS
8 Wexford Ct.
St. James NY 11780

Due to the extremely good sensitivity of the receiver on Mode B, OSCAR 7, extensive antenna arrays with high gain for the 432 MHz uplink are hardly required. In fact, excessive erp due to the use of high gain arrays by ground stations has been a problem for some time. High uplink erp causes the agc on board OSCAR 7 to desensitize the receiver, thus preventing weaker stations from accessing the satellite. Also, the batteries may be excessively drained by the high current demand, shortening their life.

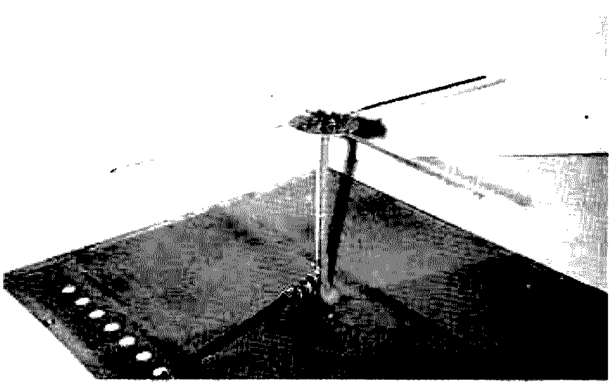
Therefore, simple low gain antennas with omnidirectional characteristics are appropriate for use on this mode. 50-70 Watts of rf into a unity gain antenna will fully access OSCAR 7 for all but the most marginal conditions. The use of an omnidirectional uplink antenna is a tremendous advantage during a satellite pass, as it eliminates the need to track the satellite in azimuth with a directional array. In addition, certain of the antenna designs described here also provide good overhead coverage. Gain arrays perform poorly at high elevation angles unless an elevation rotator is also provided for the antenna.

All the antenna types described here may be constructed for either two meters or 432 MHz. Dimensions for both bands are given in Table 1 and refer to the dimensions designated by A, B, C, etc. in the figures.

Quarter Wave Monopole

The simplest omnidirectional antenna is called the quarter wave monopole (also called the vertical ground plane), which consists of a single vertical element, one-quarter of a wavelength long, mounted over a ground plane of at least one-half wavelength on a side (Fig. 1). This antenna produces a doughnut shaped pattern with a null directly overhead and the pattern falling to zero at the horizon. Obviously, the omnidirectional term as applied to this antenna is only meaningful in the azimuth plane. Its elevation plane pattern is symmetrical but certainly not omnidirectional. This antenna becomes quite ineffective at elevation angles greater than 40 degrees from the horizon, making it almost useless on satellite orbits which pass close (up to 300 miles) to the ground station. Still, its simplicity makes it useful for some applications.

Construction of the monopole is nearly trivial — mount



Turnstile over ground plane (432 MHz).

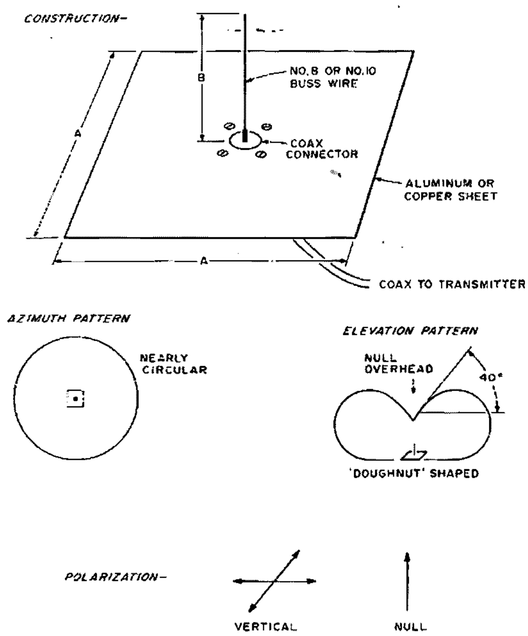


Fig. 1. Quarter wave monopole.

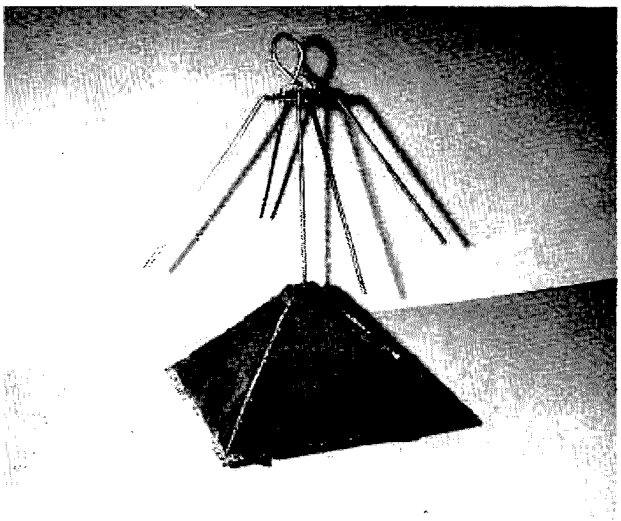
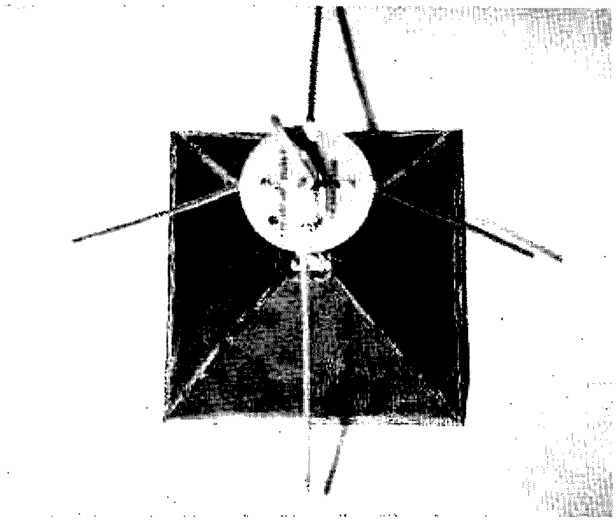


Sloped turnstile over ground plane (432 MHz).



Top view. Sloped turnstile over ground plane.

a panel-mount BNC or N connector in the center of an aluminum or copper sheet and solder a quarter wave long piece of #8 or #10 bus wire to the center pin. The vswr should not exceed 1:5 to 1 without further matching. Trimming the length of the wire will permit a closer match, if desired.

Dipole Over a Ground Plane (Fig. 2)

Another simple antenna which works well on overhead passes of the satellites is the half wave dipole over a ground plane. This antenna provides some gain (1.5-2 dB) overhead, but has nulls off its ends and near the horizon. Like the simple quarter wave monopole, it is linearly polarized (horizontal), so fading due to rotation of the satellite with respect to a ground station is still present. Manual switching between a vertical and horizontal antenna can be done during satellite passes to pick the best polarization at any given time.

In order to minimize the effect of the nulls off the ends of the dipole, this antenna should be oriented so it favors NNW-SSE (in the continental US), as most ascending node passes go out to the NNW during the evening, local time.

No balun is required. The antenna pattern may be slightly skewed, but no real advantage is gained by feeding the antenna in a balanced mode. Purists can add a quarter wave decoupling sleeve over the upright feedline.

As with the quarter wave vertical, the vswr as constructed will generally not exceed 1.5 to 1, and the dipole element lengths may be trimmed to achieve a perfect match. The spacing of the dipole off the ground plane has been chosen for best omnidirectional coverage in the elevation plane. Some gain can be achieved by varying this spacing at the expense of pattern symmetry.

The dipole elements are constructed from 1/8" diameter copper or aluminum tubing, flattened at the end and fastened to a plastic or printed circuit board disc with #4 screws. The feedline (and vertical support) is made from a length of semirigid coaxial cable (RG-405 or equivalent) which is soldered to a coaxial connector mounted on the ground plane. Do not ground the coax connector to the ground plane – it should be mounted on insulated spacers. Cut a clearance hole in the ground plane to provide connector access from the bottom.

Turnstile Over Ground Plane

A worthwhile improvement over the simple dipole may be had by adding an additional dipole fed 90 degrees out of phase to the simple dipole described above. This provides two

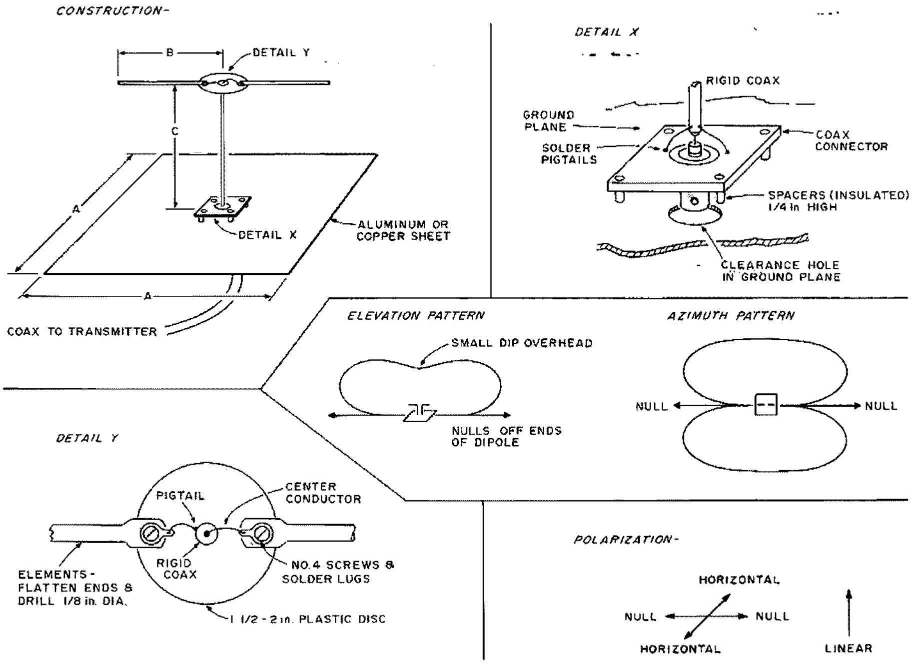


Fig. 2. Dipole over ground plane.

advantages: the antenna will be circularly polarized overhead, and the nulls off the ends of the simple dipole are eliminated, providing a more uniform azimuth pattern.

This antenna, commonly called a turnstile, has been extensively used for HF and VHF ground communications, but its major advantage is in satellite communications — circular polarization overhead is not a factor in ground communications use. Circular polarization minimizes polarization fading overhead when the satellite tumbles or rotates. Near the horizons, this advantage is lost and the antenna exhibits essentially horizontal polarization unless it is aimed at the satellite with an elevator rotator. Obviously, an azimuth rotation is of no advantage, as its azimuth pattern is essentially omnidirectional.

Construction of the turnstile is merely an extension of the technique used for the single dipole over a ground plane (Fig. 2). Two additional dipole elements are installed on the plastic disc at right angles to the original dipole (see Fig. 3). To obtain circular polarization, a one-quarter wavelength phasing line fabricated from RG-405 rigid coaxial cable is connected between the dipole elements. This phasing line is bent into a loop and supported by its solder joints. Detail X of Fig. 2 is also applicable for mounting and feeding this antenna configuration.

If the element lengths, line lengths, and spacings listed in Table 1 are used, vswr should not exceed 2 to 1 over the satellite bandwidth. A near perfect match may be achieved by trimming the element lengths and their spacing off the ground plane. Adjusting the phasing line length for perfect circularity overhead is possible but not critical in this application, as some ellipticity overhead will be of little consequence.

Sloped Turnstile Over Conformal Ground Plane

A developmental antenna presently in use at K2OVS was designed and constructed to overcome one of the major drawbacks of the antenna previously described. All the monopole and dipole configurations exhibit either *all* vertical (monopole) or *all* horizontal polarization on the horizons, thus creating polarization fading when the satellites tumble and rotate. A combination of vertical *and* horizontal polarization (*slant*) at the horizons would be an advantage in obtaining the more uniform performance for all orbiting satellite orientations.

Thus the elements of the basic turnstile were reconfigured at a 45 degree angle and the ground plane beneath them, was shaped to be parallel with each element. Overhead, the antenna is still essentially circularly polarized with slightly less (1 dB or so) gain than the simple turnstile, but the overall gain in uniform performance is worthwhile. In actual tests at this station, no measurable difference in overhead performance was observed between this antenna and the turnstile.

Basic feed and phasing line construction is identical to the turnstile (Fig. 3), and the feedpoint connector is mounted on the base ground plane similar to Detail X in Fig. 2. The elements (Fig. 4)

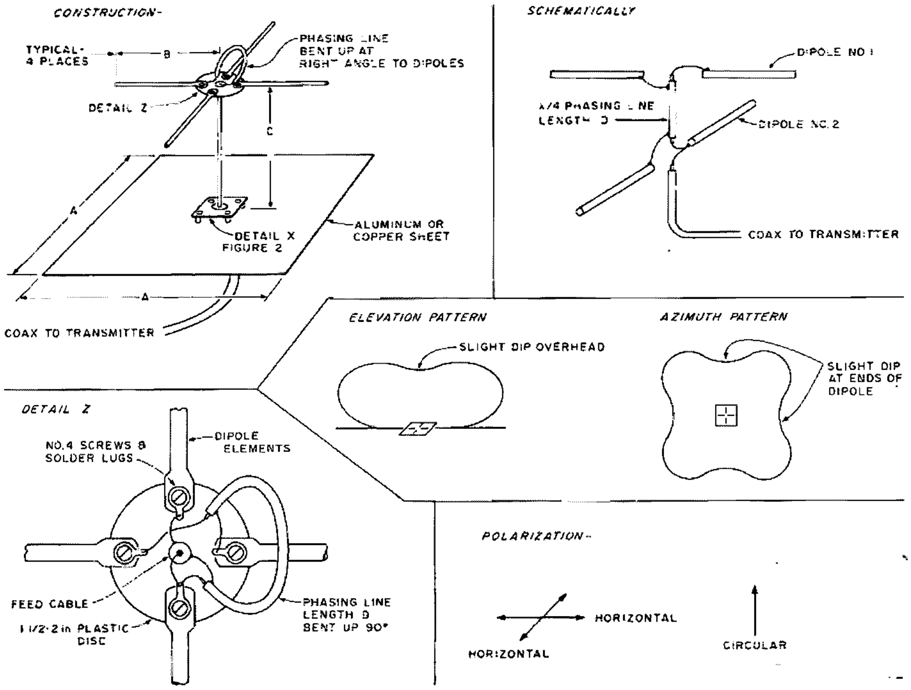

Fig. 3. Turnstile over ground plane.

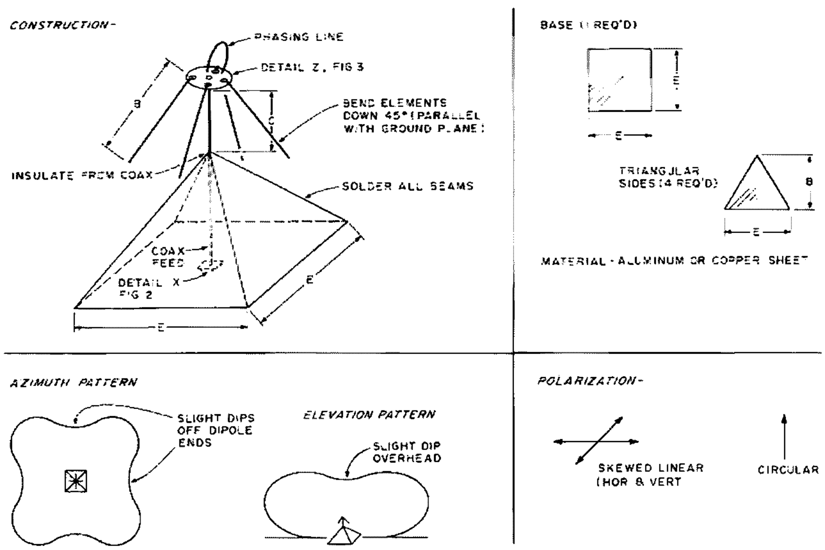

Fig. 4. Sloped turnstile over conformal ground plane.

are bent down at a 45 degree angle to the horizontal and a conformal ground plane is fabricated from either aluminum sheet or thin copper or copperclad printed circuit board material. The use of thin copper sheet allows the ground plane assembly to be soldered together with a 250-300 Watt soldering iron or torch.

Again, dimension adjustments may be required if close matching is desired. Furthermore, slight adjustments (±10 degrees) in the element droop angle will also affect the vswr (*and* the pattern). This angle adjustment should be used only as a final tune-up step. Element lengths have the largest effect on vswr.

Results from this antenna were surprising. The 432 MHz prototype was completed five minutes before a Mode B pass favoring US east coast-Europe contacts. A six-foot piece of RG-58 was temporarily connected to the antenna and the KLM Echo 70 (10 Watts output). Three western European stations were worked on that pass with no difficulty. No inference is intended that this design is the ultimate omnidirectional antenna. Rather, it is presented as an example of an unorthodox design which can serve as a starting point for further development and experimentation.

Summary

As with all antennas, good horizon coverage is a function of the height of the antenna. These antennas perform well overhead and at higher elevation angles almost independently of their physical height above ground, but performance out at 2,000 miles (satellite near the horizon) could be severely compromised by terrain blockage. Good low angle (DX) coverage is best accomplished with a unidirectional array, such as a yagi or collinear, mounted high and in the clear. An existing VHF array with azimuth control in conjunction with an omni type antenna for higher radiation angles is an ideal combination for all-around satellite work.

As stated before, the antennas described here are hardly the ultimate in omnidirectional types. Further development and experimentation is most rewarding with antenna design. For example, the sloping turnstile might be further improved by extending or reshaping the ground plane, adding an additional set of dipole elements at a 45 degree angle *above* the horizontal, adjusting the droop angle, etc. Accurate comparisons of several antenna designs can be made quite easily using the satellites themselves as an antenna range signal source. A typical pass of 20-25 minutes permits switching between the antennas under test and evaluation of the results. Modification may be accomplished in time for the next pass. The actual pattern of an antenna may be estimated by physically holding the antenna (particularly 432 MHz versions) and rotating it while pointed at the satellite (to estimate circularity), changing its elevation orientation, etc. Fading effects from the satellites themselves tend to be of relatively slow duration (3-4 minutes), so measurements or comparisons made within 2-3 minutes effectively eliminates errors caused by the satellites or atmospheric conditions.

Gain estimates for higher gain VHF arrays may also be made using the satellite by switching back and forth between a reference antenna (e.g., dipole) and the antenna under test while observing the received signal level on the station receiver. A calibrated attenuator will permit more accurate measurements. Set a level with the reference antenna, switch to the gain array, and insert attenuation in the antenna line until the received level is the same as it was with the reference antenna. The gain of the array may then be read off the attenuator dial. Obviously, different line losses must be accounted for and the polarization of both antennas should be the same.

The present OSCAR satellites are providing the amateur fraternity with a unique opportunity for VHF-UHF antenna experimentation. Future "stationary" (geosynchronous) satellites may serve as permanent antenna ranges in the sky, permitting extended development, adjustment, and measurement times for antenna work.

It is hoped that the ideas presented here will encourage further experimentation and development in VHF-UHF antennas and fill a need for the present OSCAR satellites. ■

Looking West

from page 23

way of phone service was being overloaded with traffic. Much of the communications handled by amateurs was what might best be termed of the "health and welfare" variety, permitting firefighters to get word to their relatives as to where they were, locating people for other people, etc. It should be noted that firefighters came from all over the USA, and for many there was but one way to get a message to the "folks back home": via amateur radio. Amateur communications was not limited to this small aspect, however — not by a long shot.

Both VHF repeaters and HF point-to-point were used to relay information to and from areas where the fire was being fought, relay firefighting orders, and handle just about every conceivable form of traffic that you might imagine. In all, over three hundred amateurs (under the direction of Ed Gribi, emergency coordinator for the area) from all over the state (and even from out-of-state) volunteered their services at one time or another. I am told that no offer of help was turned down.

Repeater systems served well and continue to do so. At least two machines were brought into the area by concerned amateurs who realized the communications need. One came from a group at Vandenberg AFB, and was installed at the Hunter-Liggett Military Reservation near Paso Robles, to give coverage from the Questa Grade to Salinas. Its channel pair is .28/.88, and it's under the trusteeship of W6LIO. I've also been told that the .84/.24 group out of the Bay area literally "smoke tested" their new Motorola repeater (destined for service atop Mt. Diablo) by installing it in a portable configuration at a point near the northern tier of the fire area. It performed flawlessly. Again, it's hard to know exactly what's transpiring since I am forced to report from secondhand information rather than from an eyewitness viewpoint. Suffice it to say that amateur radio and its people have done and are doing their share and more to aid in the formidable effort to stop the raging infernos. They are giving their time, talent, and equipment because there is a need and a job to be done. I am proud of each and every one of them. They know and they care. They're getting the job done.

Get Set For OSCAR 8

-- details on the new bird!

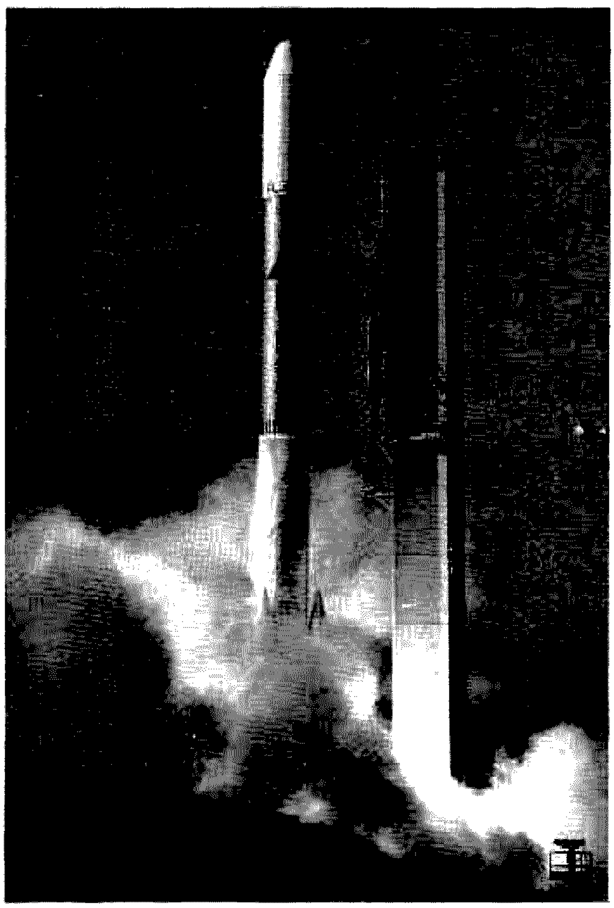

Fig. 1. Up, up, and away! This photo of the OSCAR 7 launch shows what's in store for AMSAT-OSCAR D.

Gary L. Tater W3HUC
7925 Nottingham Way
Ellicott City MD 21043

Five, four, three, two, one, blast-off! Soon a new amateur satellite will be carried into Earth orbit. Are you ready to start making contacts via this new satellite? If not, read on, and you'll discover what you need to use AMSAT-OSCAR D (to be called AMSAT-OSCAR 8 after a successful launch).

Why AMSAT-OSCAR 8?

Because AMSAT's Phase III spacecraft will not be operational until early 1980 and OSCAR 6 cannot be counted on until then, AMSAT felt that AMSAT-OSCAR 8 would provide a continuation of the existing amateur satellite program and insure that amateurs would have a reliable satellite for communications over the next few years.

One major objective of the AMSAT-OSCAR 8 (AO-8) mission is to provide a satellite for use as an educational tool in schools. Other objectives include the continuation of demonstrations by stations in the amateur satellite service, experimenting with the feasibility of using satellites with small amateur terminals for bush communication, emergency communication, communication between medical centers and isolated areas, aeronautical, maritime, and land mobile communications, direct satellite to home voice broadcasting to simple amateur receivers, and other similar applications. Further objectives are to demonstrate special operating techniques that enhance the usefulness of low orbits for these satellite applications and to test a new communications transponder frequency combination for improved operation for moderate power amateur stations.

Building the Satellite

For longer than a year now, AMSAT members from many countries have been planning, designing, and building a satellite called AMSAT-OSCAR D. Because a project like this is extremely complex, it takes many amateurs, pooling all their knowledge and abilities, to turn the stringent design and reliability requirements into a ready-to-launch satellite.

Some of the complex issues that had to be settled and turned into hardware were the receivers and transmitters for the transponders, the antennas and antenna deployment system for the large antennas, the satellite stabilization system, the power system, and hardware both in the satellite and on the ground for commanding the satellite. As a user, you're primarily concerned with the transponders that make satellite communications so much fun, but there are really eleven major subsystems in AO-D:

1. 2m to 70 cm transponder;
2. Two to ten meter transponder;
3. Morse code telem-

1. **Japan AMSAT Association 2m to 70 cm Transponder — Mode J**
   - Input frequency passband between 145.90 and 146.00 MHz.
   - Output frequency passband between 435.10 and 435.20 MHz.
   - Power output is 4 Watts PEP.
   - Downlink passband is inverted from uplink passband.
   - Linear operation — SSB and CW are preferred modes.
   - Morse code telemetry beacon at 435.095 MHz.

Building a satellite like AO-D proceeds pretty much along the same lines as most electronic projects do. First, each electronic system is tested as a breadboard and then laid out for a printed circuit board. To insure that the satellite functions reliably for years, each integrated circuit, transistor, and diode is screened by burning the part in by applying power to the part for several hundred hours. Then the component is mounted onto a printed wiring board. After each system is mounted in the satellite structure, the satellite is tested under the vacuum conditions and temperatures it will see in space. Because amateur satellites are launched on a space available basis, they are mounted on the launch vehicle neatly tucked under the primary satellite as you can see from the accompanying pictures. In Fig. 3 you can see Dave W6OAL inspecting the electrical connections for the pyrotechnical shears which, when fired, cut the Marmon clamps that released OSCAR 7 from the Delta launch vehicle. A heavy duty spring then ejects the satellite into its orbit path. A few seconds later, the ten meter antenna is deployed by a pyrotechnical shear mechanism aboard the spacecraft.

Getting Ready

There will be two communication transponders on AO-8 for which you will need equipment. Only one transponder will be operated at a time because of spacecraft battery constraints.

The Mode A transponder is a two to ten meter unit similar to the one on AMSAT-OSCAR 7 and has the same frequency plan (input frequency passband between 145.85 and 145.95 MHz, output frequency passband between 29.4 and 29.5 MHz). You should plan to use about 80 Watts erp made up of output power from your transmitter, coax cable losses, and antenna gain. A ten meter preamp should stand you well for copying the Mode A downlink.

The second transponder, constructed by members of the Japan AMSAT Association in Tokyo, uses a two meter input, 435 MHz output frequency combination which has not yet been flown in the AMSAT Phase II series. This transponder, designated Mode J, operates with an input frequency passband of 145.90-146.00 MHz, and an output frequency passband of 435.10-435.20 MHz. The power output is 4 Watts PEP, so a small 435 MHz antenna should produce a strong signal to your receiver. As noted in Table 1, the output passband is inverted, i.e., upper sideband uplink signals become lower sideband downlink signals. The same transmitter you use for Mode A can be used on Mode J.

Table 2. Morse telemetry channels.

Antennas

In general, simple antennas such as ten meter dipoles and four element 2m and 70 cm beams will provide excellent results. The AO-8 Mode J 435 MHz downlink antenna is a simple monopole and will provide a linearly polarized signal. Likewise, the spacecraft's Mode A ten meter downlink antenna is a linearly polarized dipole, oriented perpendicular to the stabilization magnet in the spacecraft as in AMSAT-OSCAR 6.

Although you can transmit on two meters to the satellite using a linearly polarized antenna and get good results, if you are a perfectionist, you might like to try circular polarization.

Both the Mode A and Mode J transponders on AO-8 use the same receiving antenna, a canted turnstile comprised of four 18-inch lengths of ½-inch carpenter's rule fed by a hybrid and matching network so as to develop circular polarization. One port of the hybrid feeds the Mode A receiver such that

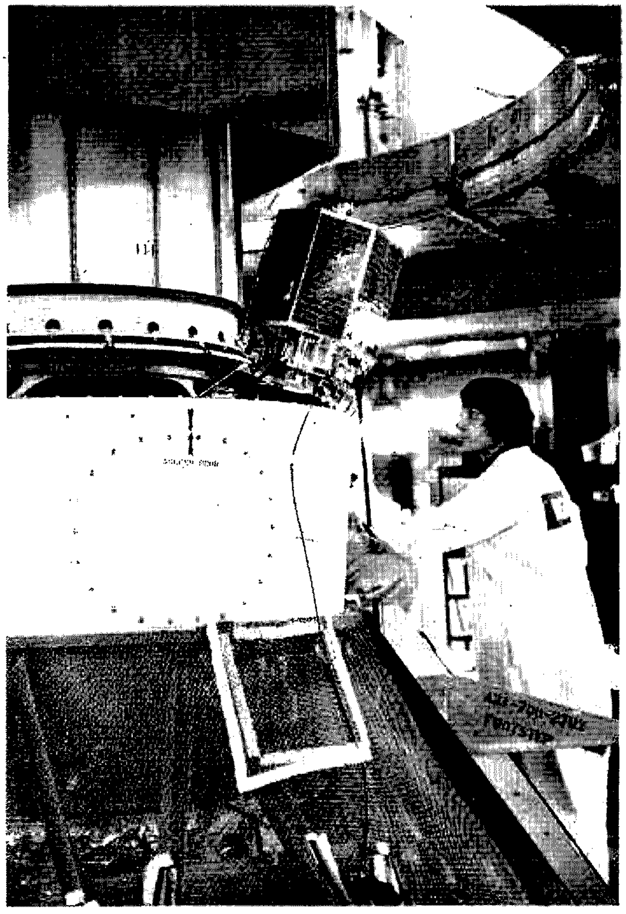

Fig. 2. Jan W3GEY inspecting OSCAR 7 on the Delta launch vehicle.

left-hand circular polarization is required by users in the Northern Hemisphere and right-hand circular polarization in the Southern Hemisphere. A second port of the hybrid is connected to the Mode J receiver such that right-hand circular polarization is required in the Northern Hemisphere, and left-hand circular polarization in the Southern Hemisphere.

Telemetry System

So that everyone can watch the status and health of the spacecraft, AMSAT-OSCAR 8 will contain a six channel Morse code telemetry system. The Morse telemetry on 29.40 or 435.095 MHz will be set at 20 words per minute, but you can slow it down by recording it and playing it back at a slower rate. You will hear the telemetry as three digit numbers with the first digit being the channel number and the next two digits being the telemetry value. A sample telemetry frame would look like this: 120 255 380 451 551 660 HI 120 255.

Although the equations to convert the telemetry values to engineering units have not been finalized as of this writing, the channel selections have been made and they are listed in Table 2.

Using AMSAT-OSCAR 8

Once AO-8 becomes operational and you've assembled your station, you can begin to make contacts picking up new states and countries each time you get on the satellite. If you need help, contact AMSAT at Box 27, Washington DC 20044 for the name of the nearest AMSAT Area Coordinator who, as an experienced satellite user, can give you a hand.

In addition to making contacts and working new states through the satellite, AMSAT hopes that you will consider using AMSAT-OSCAR 8 to perform experiments and educational demonstrations. These efforts gain amateur radio much needed beneficial publicity and provide AMSAT with documented facts to support requests for future launches.

Your experiments might begin with such simple experiments as using a power meter to plot the minimum power needed to hear your return signal in the downlink from your earliest acquisition of signal to loss of signal. Possibly you could measure the frequency change in the beacon due to the Doppler effect of the satellite's velocity.

As a guide to what you can do with AO-8, other experiments are listed in Table 3. Perhaps you can add some interesting experiments to this list. When you complete an experiment, be sure to write to AMSAT with your results, you will be contributing to the future of amateur radio.

Conclusion

If you are already a user of OSCAR 6 and OSCAR 7, then you're set to operate through OSCAR 8, and you know how exciting satellite communications are. If you are not ready for OSCAR 8, then now is the time to get your station ready to join the fun. See you on AMSAT-OSCAR 8! ■

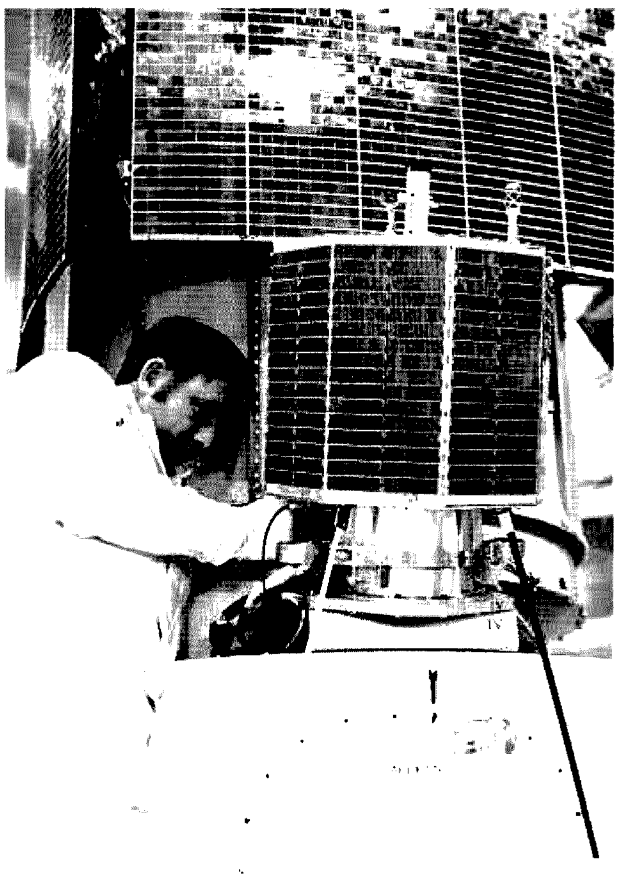

Fig. 3. W6OAL puts the finishing touches on AMSAT-OSCAR 7.

A) Educational demonstrations in schools and for youth groups.
B) Ranging (distance measurement) experiments to determine satellite or user position.
C) Doppler (range rate) measurements to determine satellite or user position.
D) Emergency Locator Transmitter (ELT) experiments to locate downed aircraft or ships in distress.
E) Small terminal user experiments using hand-held equipment, or mobile terminals operated from an automobile, airplane, boat, motorcycle or bicycle.
F) Emergency communications demonstrations with portable equipment.
G) Medical data transmission experiments, including the transmission of analog or digital physiological data (e.g., ECGs and EEGs).
H) Data collection from remote, unattended ground terminals (rain gauges, wind gauges, etc.).
I) ASCII data transmission experiments, including remote accessing of digital computers.
J) Slow scan and medium scan television experiments.
K) Remote control experiments (such as radio control aircraft, garage door opener, remotely controlled kitchen ovens, etc.)
L) Transponder interlinking experiments between AO-7 Mode B and AO-8 Modes A and J.
M) Multiple access experiments (such as quantitative experiments to evaluate the effects of power sharing with different modulation techniques).
N) Ground station automation (closed loop monitoring of downlink signals and automatic adjustment of uplink power and frequency).
O) Broadcast demonstrations using the transponder in a single access mode, evaluating performance for different modulation modes.
P) Extended range communications experiments to attempt transmission or reception beyond the normal maximum satellite range.
R) Low power (QRP) user experiments to determine the minimum power needed to sustain communications.
S) Traffic nets scheduled on the satellite.
T) Automatic tracking of ground station antennas in azimuth and elevation (either on an open loop or closed loop basis).
U) Unattended, automatic telemetry data collection (e.g., using tape recorders for later analysis).
V) Unattended online or offline computer processing of received Morse code telemetry data, with printout of parameter values and units. Automatic decoding of Morse code characters in the presence of noise.
W) Experiments involving physical parameters, e.g., determination of spacecraft spin characteristics and orientation from telemetry data.
X) Traffic handling with RTTY using autostart techniques.

Build An OSCAR 2m Transverter

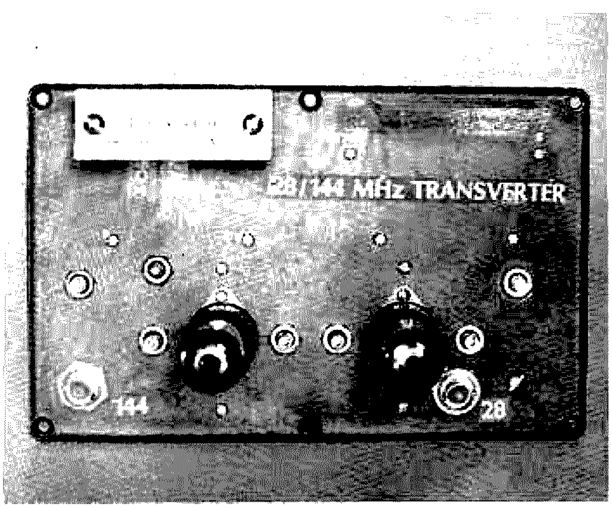
-- make QRP days a success!

There are in use on mode B of OSCAR 7 possibly 200 28-432 MHz transmitting converters made originally by the Carmichaei Communications Co. and more recently by the Amateur Radio Component Service. Using an antenna system with a modest gain, with 4 to 5 Watts output on 432 MHz, these converters seem made to order for low power satellite operation. There are many mode B users who will attest to their performance. W1NU, for example, made about 200 QSOs on mode B with this converter and a mediocre antenna during his 1976 Bermuda jaunt. Considering the successful track record of this converter on 432, its SSB capability and the improved tube performance on 144, the idea of building a 2 meter version was attractive.

The circuitry of the two meter model, shown in block form in Fig. 1, is the same as the 432 model except for the elimination of one stage in the LO chain and the appropriate changes in the LC elements.

The schematic, Fig. 2, illustrates the simple straightforward design characteristic of this converter. A voltage doubler circuit off the 6.3 V ac line provides the voltage for both the 2N4126 and the 2N3866 stages and also the adjustable bias for the 6939 amplifier. Zener regulation is used for the amplifier screen and for the crystal oscillator. The mixer is cathode biased. Input jack J1 is terminated with a 62 Ohm resistor, which may be disconnected if the drive is too low with it in place. A 58.9 MHz crystal may be used if the available driver does not have 29.5 coverage. This will give a mixing frequency of 28.1 MHz for an output on 145.9 MHz.

Construction details are shown in the photos. The unit is built on a Bud CU247 cast aluminum chassis, using the top as a mounting base. A brass partition lengthwise isolates the LO chain, which is built on a circuit board. The mixer and amplifier shielding is provided by two lateral partitions. Five small brass tabs on the partitions provide a connection to the bottom of the chassis to complete the shielding when the unit is placed in the case. Although the construction is a bit fussy, experienced builders will have no difficulty in duplicating either the 2 meter or 70 centimeter converters. For those interested in building, a complete set of information, drawings, and photos covering the two meter converter (and its 220 MHz and 432 MHz counterparts) is available from ARCOS, PO Box 546, East



The complete transverter.

Greenbush, NY 12061, for $5 (to cover costs and postage). These converters are also sold by ARCOS as assembled and tested units.

For alignment, an output indicator of some kind is needed, and it is best to also have a two meter receiver tuned to the output frequency (observing the S-meter as a tuning indicator). The oscillator and doubler stages may be tuned using an rf probe and meter to maximize output. A counter, if available, coupled loosely to L2 will confirm that the mixing frequency is correct. The rf voltage at the point of connection to the output coax from the circuit board should be 5 or more volts ac. The mixer and amplifier stages of the two meter version of this converter do not appear to have any instability problems, although there is a tendency to oscillation if the mixer grid circuit is mistuned to approach the operating frequency. Spurious outputs, with proper alignment, appear on the Tektronix L-20 to be over 40 dB down. At this low power level, interference with other two meter operations is unlikely and, at least in the Albany NY area, has not been experienced. (More than we can say for some commercial units we have tried to use for satellite work.)

If you haven't yet tried low power, there are still some surprises ahead for you in satellite operation. ■

Predicting OSCAR Propagation

-- not always simple

The earliest case of unexpected radio propagation from an artificial satellite took place in early October, 1957, soon after the launch of SPUTNIK 1. Radio amateurs observed good copy of the world's first man-launched satellite on 20.005 MHz when it was on the opposite side of the Earth to the listener, but not always when it was to be expected, coming up over the horizon. Those observations made during the relatively short life of the spacecraft tended to indicate that good conditions, e.g., a high MUF, were coincident with both of the noticeable effects. Sub-F2 layer reflections during the high sunspot years with the consequent high level ionization were apparently responsible for the antipodeal signal, with the attenuation of lower layers limiting the signal at low angles when the maximum density path was between the beacon and the listener.

A similar effect was apparent on some of the earlier ten meter beacon OSCAR spacecraft.[1,2] With the advent of the OSCAR 6 and 7 Phase II spacecraft in high orbit, well above the maximum possible F2 layers and launched during low sunspot years, similar happenings could hardly have been predicted. Although infrequent, such abnormalities have been evident.[3,4,5,6]

Evidence of beyond-the-horizon audibility of both the 145 and 435 MHz beacons is very rare, but early hearings and late losses have been reported, although rarely for more than three minutes from the calculated AOS or LOS time. One would hardly expect effects like forward scatter to be evident when the signal source is of less than one Watt erp due to the attenuation placing the small signal source well below the noise level at the receiving end.

There is, however, considerable evidence of the two meter uplink of OSCAR users accessing the satellites for up to seven minutes after the time when, according to path theory and calculation geometry, the signal should have ceased to be transponded by the spacecraft. They, regrettably, fell far short of the thirty minute extra presence of the 29 MHz

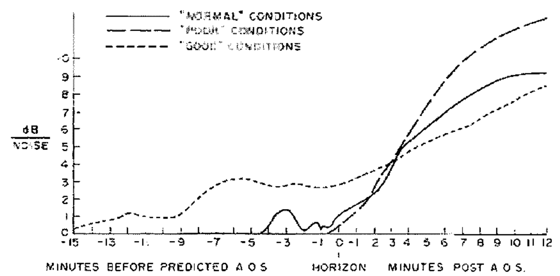

Fig. 1. OSCAR 7 29.502 MHz beacon downlink strength through time in typical different conditions (HF).

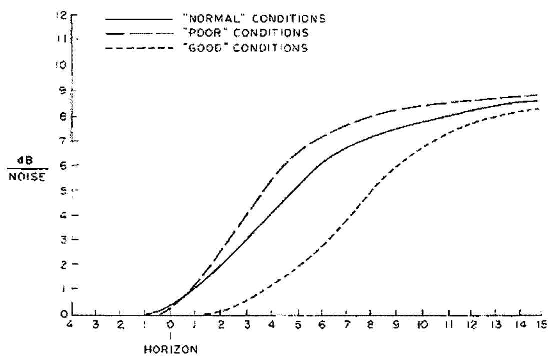

Fig. 2. OSCAR 7 returned (145.95 MHz) signal on 29.5 MHz downlink in typical different conditions (HF).

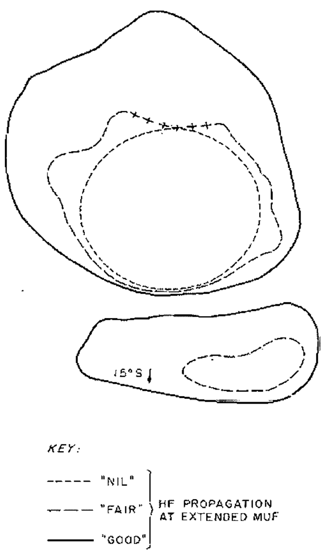

Fig. 3. Contour mapping of maximum distance AO-6 and AO-7A 10 meter detection on polar equidistant projection. Polar areas of no subsatellite points are marked "+" as these are non-definable. Note the distortion of horizon radius circle. This is an effect of using an equidistant projection centered on the pole axis. A stereographic projection would show a true horizon circle, but its center would not be at the observer's specific QTH. A great circle map centered on the observer's QTH would form a true circle with location center, but would further distort distant contours.

downlink, though, and rarely accessed both at the same time.[5,6]

Equally unfortunate is the fact that rarely does the 432 MHz uplink seem to exceed the line of sight by more than about one-and-a-half minutes, within the limitations of my experience.

What appear to be anomalies between the various frequencies' behavior patterns and the apparent contradictions to currently accepted textbook theories may be the subject of a future article when a sufficiency of data has been gathered to give a reasonably statistically sound degree of collated evidence. Already the information obtained and its relationships to other phenomena of interest to the radio amateur are enough to show the value of the OSCAR satellites in fields other than those of through-satellite communication alone.[7]

The following associations between what can be found by listening and using OSCAR for two-way communication, and what may be forthcoming by way of HF, VHF, and UHF (including the effects of aurorae, tropospheric and sporadic E in communication conditions), will be evidenced in an attempt to show that the amateur radio satellites can give a valuable pointer to assist those keen to exploit the improved, and in some cases impaired, propagation that is effected.

The Standard

Many means of extrapolating the precise crossing times of the satellite over one's horizon, calculated from the equatorial satellite crossing time and position,

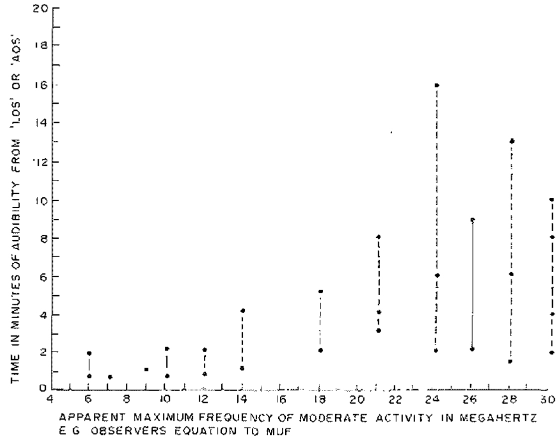

Fig. 4. Plot of all values of extension to horizon to MUF apparent.

now exist.[8,9,10,11,12,13,14] The relationships that I shall use are those related to my own QTH/QRA, just North of Norwich, Norfolk, Eastern England, at 52° 40' N, 1° 10' E. For fine precision, albeit marginal in the wide field employed, the station's height above sea level plus the antenna height is given as 160 feet. With no hill higher than my elevation within the horizon curve, we may evaluate an addition as: $H = 1.42 \sqrt{E}$, where H is the horizon extension in miles, and E is the elevation above sea level in feet. In my case $H = 1.42 \sqrt{(95 + 65)} = 18$ miles. That is neither here nor there in terms of the 3000 mile slant range of OSCAR at horizon, but could add considerably to those in mile high cities like Denver and Mexico. Any blocks to true horizon may be found by the examination of contour maps and plotting out the height against distance on graph paper to find the true contours of the radius of true horizon around one's QTH. (Fortunately, flat old Norfolk suffers from no high hills.)

We now have a means of finding the precise time, say plus or minus 15 seconds, when the satellite comes into our capture. If there is no barometric lift, minimum solar activity, and it is well into the night, OSCAR will appear exactly on schedule, almost simultaneously on the 29.502, 145.971, and 435.1 MHz beacons. One's 432.125-175 or 145.900-146.000 (OSCAR 6) or 145.850-950 MHz (OSCAR 7 mode A) uplinks will appear as transponder output at almost the same time. Any deviation of these times, relative to each other or to the calculated, will indicate an anomaly and show an alternative to "no propagation" conditions.

High Frequency Conditions

Although the variation on calculated AOS and LOS times is not always consistent, the general and average effect may be seen on the graph values of Figs. 1 and 2. At this point let me say that I do not feel that a sufficient number of measurements have been taken to fully substantiate the effect, as time, particularly during daylight hours, is very limited. Furthermore, a number of specific variables need to have attention, e.g., the path preference of normal HF communication at the time of measurement, the skip distance, and a further relationship to the time of year. It did seem that ultra-distant OSCAR audibility was more consistent with short skip conditions, i.e., ionization of the lower layers, than with long skip propagation associated with the F2 layers. But more work needs to be done on this subject. What was apparent from the orbits sampled was threefold:

1. The higher the apparent

usable frequency was, the weaker the OSCAR downlink signal was on 29.502 MHz prior to horizon loss of signal predicted time, and the weaker it was at post-horizon at acquisition of signal times.

2. The increase of maximum usable frequency for HF communication was indicated also by the strength of the downlink signal prior to expected AOS and after expected LOS.

3. The high frequency propagation possibilities tended to coincide with an increase of the time for which the ten meter downlink and beacon were audible both before official AOS and after its LOS.

A further factor is the increase of noise, both on the downlink frequency band itself, and upon the transponder's own downlink.

At this point, two requirements must be pointed out. The first is that the observer must be equipped with a reasonably high antenna, preferably with some gain, as high gain at low angle is an essential to observe these proximate-to-horizon effects. It is assumed that the keen DXer will have this requirement. Second, it is normal to copy reasonably good signals both before and after the above-horizon transit for up to three minutes if the path is in daylight. In low MUF dark path conditions, the signal will normally extinguish promptly at the predicted LOS and arise promptly at AOS. We may summarize by saying that the longer and slower the beacon signal decays, the better the predictor value for favorable HF conditions.

Fig. 3 shows the contour lines found at this QTH with the extra path OSCAR detection, i.e., anything observable above noise in three sets of subjective HF propagations. These are grouped into "good," shown by the continuous contour, "fair," as shown by the dashed contour, and "nil," as shown by the dotted line, which equates the line-of-sight path to the satellite.

While we are dealing with HF conditions, let us mention that curse to the HF man, and the blessing to the VHF enthusiast — aurorae. The period leading up to an aurora will commence with an elevation of the symptoms of good conditions, with an added symptom of greatly increased noise and a marked deterioration of the quality (to use another subjective term) as the satellite nears the polar areas. Immediately preceding the actual event, transponded signals will be all but wiped out by noise and suffer from severe particulate modulation sounding like an old spark transmission. The signals may still be heard post-horizon in the noise for up to several minutes before total loss. More will follow on this subject in the VHF context.

Very High Frequency Conditions

The main indicators of VHF openings are:

1. A severe attenuation upon one's own returned signal, with marked fluttering and very rapid QSB at high maximum to low minimum values when the satellite is at low elevations, i.e., just over the horizon at both AOS and LOS times.

2. A marginal sub-horizon access with the signal popping up suddenly for very brief periods prior to and post the expected path times.

The beacon at these times is marginally affected also, but not to anywhere near the extent of the uplink signal. With increasing elevation, the evidence decreases proportionately. At high altitudes, the effect is virtually unnoticeable, and a normal access proceeds. To differentiate between the HF effect and the VHF effect, which do not always go together, it is necessary to alternately monitor one's own returned signal, and relate this to the beacon for comparison. To the observer, the transponded signal, even in good VHF openings, will rarely be heard more than two to three minutes at best on the downlink at extra horizon times, although other observers closer to the downlink have reported continuing copy for up to seven minutes after

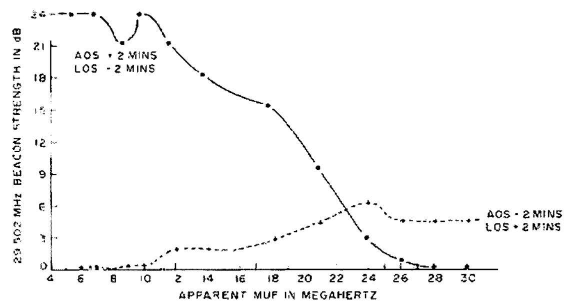

Fig. 5. Mean average signal strength of beacon to apparent MUF of same values.

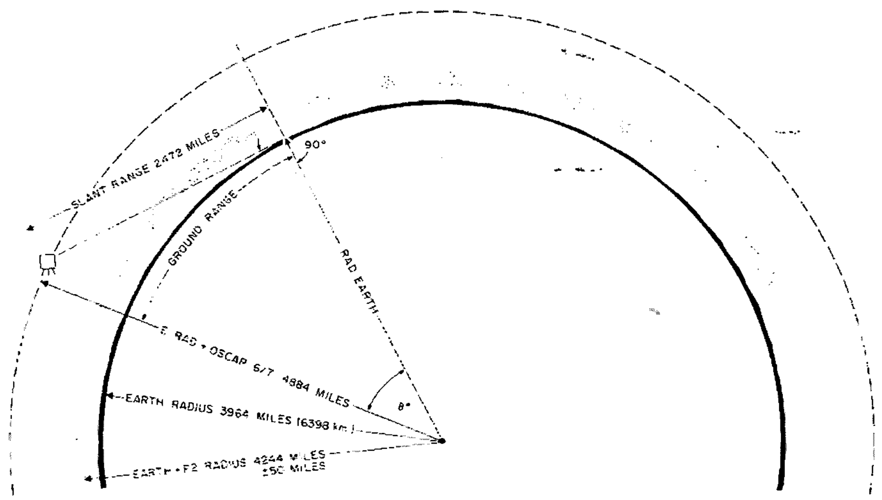

Fig. 6. Horizon geometry. True line-of-sight path calculations and structure for control use. For ground range (subsatellite point to observer) (for use on great circle map), multiply Earth radius by angle formed by it and OSCAR radius in radians. This angle = Θ = $\cos^{-1}$ of Rad Earth/Radius OSCAR = 3964/4884 = 0.8116298 = cos Θ = arcos of 0.81163 in radians = 35° 45' = 0.6238 radians. 0.6238 x 3964 = 2472.7432 miles on great circle + extra horizon.

For horizon crossing point (by Pythagorus): Draw line from Earth's center to surface = Earth radius = 3964 miles (mean). Draw line from Earth's center to OSCAR = satellite path radius = 3964 + 920 = 4884 miles, which is the hypotenuse of the right angle triangle with 90° at the observer's point when "seeing" the satellite at horizon. $H^2 = A^2 + B^2$ ∴ rad. OSC^2 = rad. $Earth^2$ + slant $range^2$ ∴ rad. OSC^2 - rad. $Earth^2$ = slant $range^2$ = $4884^2 - 3964^2$ = 23853456 - 15713296 = 8140160 miles. $\sqrt{8140160}$ = 2853 miles = slant range.

official extinction. It is also apparent at times of good tropospheric conduction that the predicted beam path is not always true. A swing of the beam carrying the uplink signal will often improve the downlink strength considerably by up to a 20° variation in azimuth and some 30° in elevation. The normal polarization preference roll pattern[15,16,17,18] is broken, with quite rapid changes in the preferred linear horizontal or vertical normal pattern that is usually serialized.

The above effects mainly apply to characteristic behavior indicating tropospheric openings.

With sporadic E, the effects are similar, but, instead of the usual evening effects, are more normally present in the central day periods. Now the flutter and rapid fading is far more intense and takes place when OSCAR is at quite high elevations. Sudden extinction and pop-up of the uplink signal is far more evident. Observation of the VHF beacon also shows a similar pronounced effect, which, like the VHF uplink, is also subject to irregular polarization fluctuations at high elevation angles.

Aurorae produce a degree of degradation on the stability and tone of the VHF beacon as the satellite nears the auroral zone. But what are far more distinctive are the isolated uplink returns, which may be quite separately effected with a tone "A" return on the ten meter downlink.[19,20] Often under auroral conditions, even separate GM stations have been observed with the characteristic auroral note, while other northerly stations have been virtually free and other more southerly stations totally free. This indicates that aurorae can be quite specific to a relatively small area, which is surprising, but readily and frequently observed. OSCAR gives a means for the early detection of forthcoming auroral openings prior to the spread to one's parochial observance area on the direct path. An even earlier indication can be given by the follow-on of a period of high MUF conditions due to enhanced solar activity by following the post-horizon ten meter signal, followed by northerly scintillation and tonal degredation.

Ultra High Frequency Openings

Ultra high frequency openings are difficult to detect by the exclusive use of OSCAR, but some small extension to the normal line-of-sight path can be detected for periods of up to one minute. What is more noticeable is the slow rise of the transponded uplink signal returned down on the two meter band, as distinct from the more usual sudden arisal of the downlink. When openings are imminent, rapid flutter coupled with some difficulty of access at very low angles is observable. Possibly a better method is to calculate when stations in the workable area will be beaming at low angles over the top of your QTH as they track OSCAR, and place your receiver on that frequency corresponding with the appropriate uplink frequency on the 432.125 to 432.175 MHz input to that of the 145.875 to 145.925 MHz downlink upon which you are hearing them, allowing for the Doppler shift.[21] It is quite amazing how many openings occur at 432 MHz when no QSOs are evident upon the normal direct path frequency range. It seems many listen, but few transmit, so everyone assumes the band to be dead. OSCAR

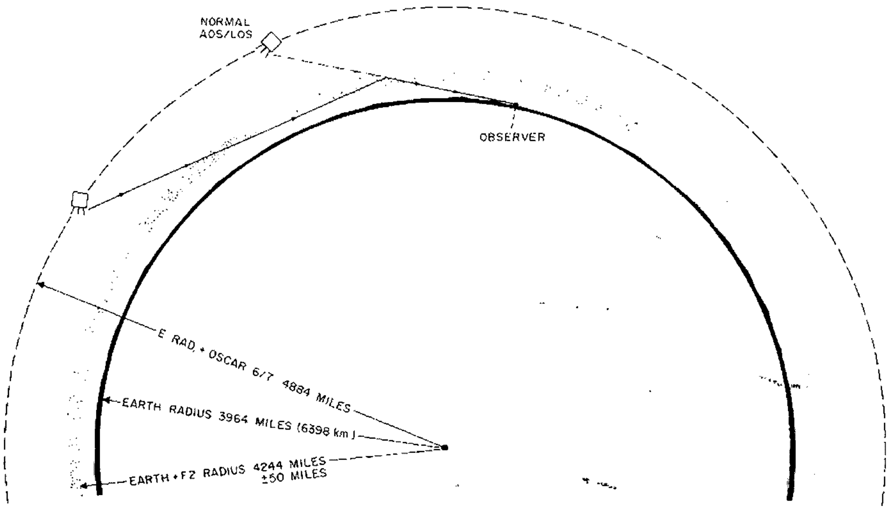

Fig. 7. Possible theory for sub- or post-horizon audibility: At high MUF (dense ionospheric layer) times, the OSCAR signal may enter via less ionized areas according to solar-radiation points. This is thought to be unlikely as its observed signal strength is greater than that expected by such a path.

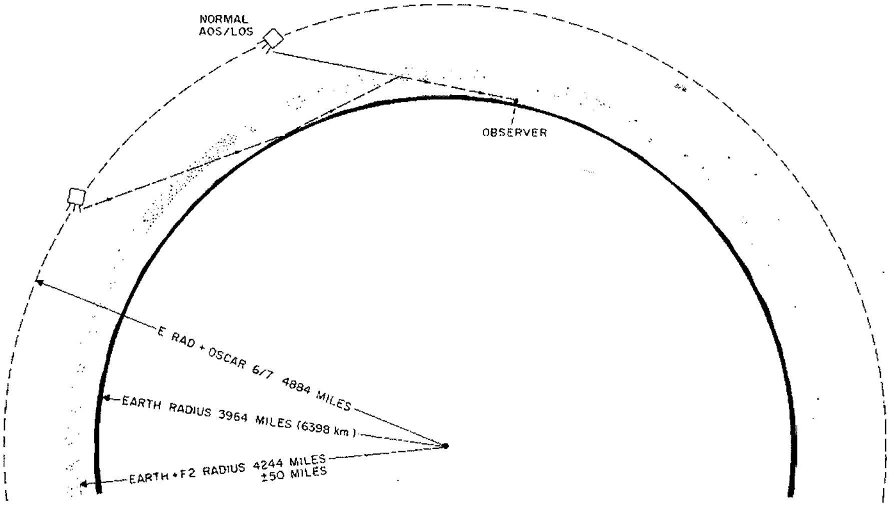

Fig. 8. OSCAR signal may enter through a low ionized area, reflect from Earth, and then return to a reflective F2 area to be returned to observer. This is highly unlikely as signal strengths are far in excess of those expected (if any).

produces known activity on known frequencies with known beam directions and gives a valuable guide to the state of the band.

The theories that may be advanced for the particular effects found can be numerous and complex. The number of variables are considerable, and an insufficiency of observations have taken place to fully define any one single cause, let alone the multiple associations probable. It is hoped that perhaps someone with the time and equipment available may wish to take the investigations over. Ideally, he would be equipped with ionospheric sounding equipment, fine Doppler measurement for determining position and path, and narrow beam antennae. This article is intended to stimulate this approach, as well as to show readers that, whatever their field of interest within the wide framework of amateur radio, the AMSAT-OSCAR spacecraft are a valuable potential asset to their particular aspect. ■

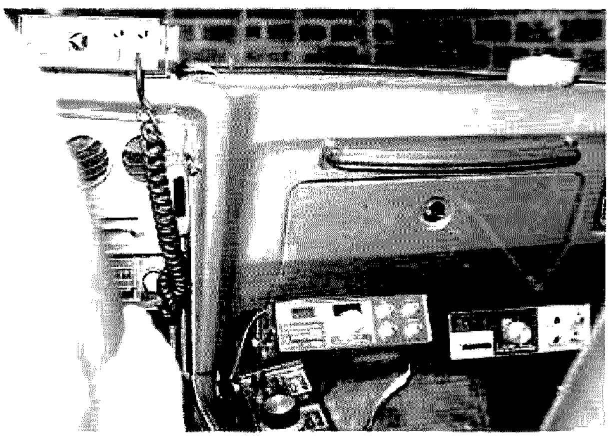
Try OSCAR Mobile

-- the ultimate DX test!

The availability of amateur radio communications via satellite has opened up an entirely new medium for reliable, long or short distance vehicular communications. The amateur radio mobile station equipped for satellite communications is no longer limited by the range of terrestrial FM repeaters, location, or HF propagation vagaries. For example, K8MYN, using the simplest equipment in his vehicle, was able to maintain consistent contact with the USA via the OSCAR 6 satellite from northern Canada and Alaska, when poor propagation conditions in that area rendered the HF amateur bands useless. Other amateurs have successfully used the satellites to communicate from a boat in the Florida Keys, from an airplane over the Pacific, and from various automobile installations. The purpose of this article is to discuss how the OSCAR satellites may be used from a vehicle and give some examples of equipment arrangements and antennas which have been found workable.



Today's equipment — 3 transceivers: 2m, 70 cm and low band. The 2m FM is in the upper left. Solid state amplifiers for the 2m and 70 cm are in the trunk. Antennas: 5/8 wave for 2m and 70 cm; Hustler for 10m and other low bands.

Fig. 1 illustrates the basic concept of mobile to base station communication via satellite. The uplink and downlink frequencies are widely separated, yielding, without filters, a built-in duplex operation. You are, therefore, able to hear not only the signals of the station you are talking to, but your own signals as well – giving a continuous indication of how well you are accessing the transponder in the satellite.

The current OSCAR 6 and 7 satellites are in approximate polar orbits at 900 miles above the earth. Both complete their orbits in about 1 hour and 55 minutes, advancing about 30 degrees of west longitude with each south to north equator crossing. For each *overhead* orbit, they are in good signal range of the relatively limited capability of simple vehicular antennas for about 15 minutes. There will also be about 10 minutes of good signal strength on the orbits two hours before and two hours after the overhead pass.

Thus, for OSCAR 6 and 7, there have been three usable orbits in the evening for the south to north equator crossings and three in the morning for the north to south crossings. This yields for both satellites about two hours total communication time for a 24 hour period. The overhead orbits occur about 9 am and 9 pm local time. There are some variations to this pattern which we don't need to go into here. A vehicular station in the polar regions will access the satellites on every orbit.

To know what time to use the satellites at your location, you keep in the vehicle a table published by W6PAJ showing the time of the equator crossing and the west longitude for every orbit for every day of the year. To the equator crossing time, you add the time for the satellite to come within range. For example, at Albany NY, for an overhead or nearly overhead pass, 4 minutes are added to the published equator crossing time for the evening passes and 34 minutes to the morning crossing time. These times, from experience, allow the satellite to get high enough in the sky to be readily

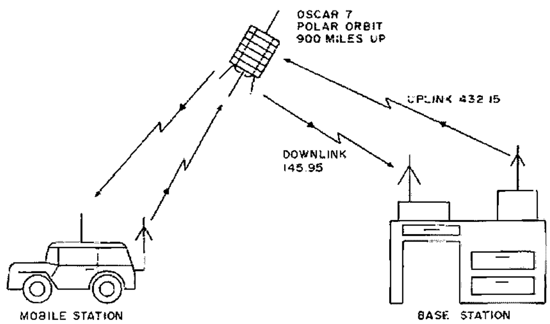


Fig. 1. Mobile to base station operation via satellite.

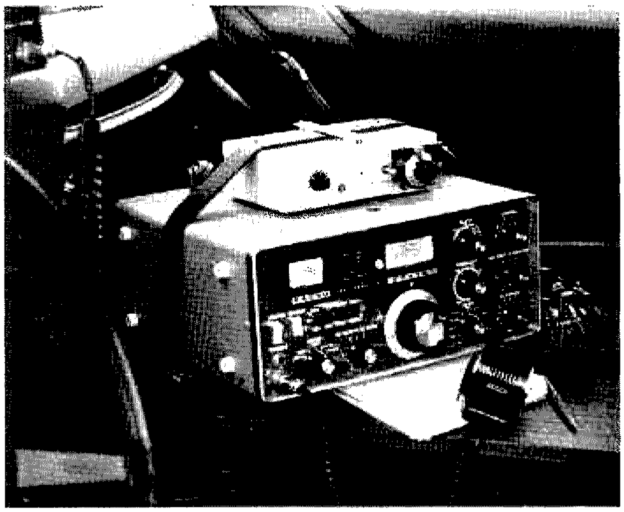
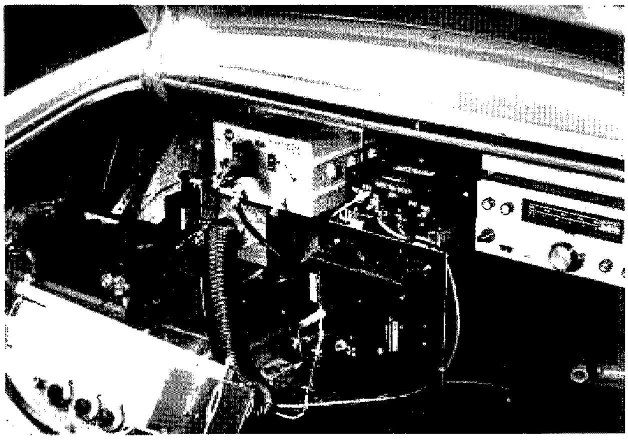


Transceiver as in Fig. 3 showing the tunable receive converter on top of the FT101.



Power amp on 432 as in Fig. 3. There are 2 power supplies — 12 V dc to 300 V dc and 12 V dc to 1600 V dc — and a 12 V to 115 V ac converter. That's a lot of equipment to generate a 100 Watt plus SSB signal on 432.150.

accessible from the car antennas.

The conservative range over which you can "see" or access the OSCAR 6 and 7 satellites from a vehicle is a circle centered on your location about 2000 miles in radius. If your location is free from obstructions, you will be able to hear your own signals return from the satellite at this range and be able to communicate with any station having an overlapping range during the period of the overlap.

With regard to the mode of transmission, the linear transponders in the satellites will retransmit any mode that is offered. To conserve power and bandwidth, SSB and CW (Morse code) are the preferred modes.

OSCAR 7 Mode B has produced outstanding vehicular communications. Based on calculations by Perry Klein of AMSAT, Table 1 shows the link calculations for Mode B using experimental equipment in my car as an example.

With this brief background of how vehicle communications are established through the OSCAR 6 and 7 satellites, we now describe some equipment arrangements in the vehicle which have been used successfully.

In March of 1973, a few months after OSCAR 6 was launched, the equipment shown in Fig. 2 was installed in my automobile. For the uplink, the equipment consisted simply of a regular amateur type 10 Watt FM transceiver, equipped with a couple of crystals in the uplink passband and arranged for keying the driver stages. An 80 Watt solid state amplifier was located in the trunk. A standard 5/8 wave base-loaded whip was the antenna.

For the downlink, a common amateur band transceiver tuned to the downlink frequencies around 29.5 MHz and a loaded whip cut to this frequency did the job very well.

The first use of OSCAR 6 from a vehicle was made with this simple setup. Over a two year period of operation on the road in various states here in the East, it was very effective, accounting for hundreds of contacts with other amateur radio operators all over the USA and Canada, as well as a few contacts with Europe. The excitement of these early operations with OSCAR 6 will be long remembered by those who participated. This operation was all done with a telegraph key — not the best mode from a moving car. Practically all operation was, in fact, done with the car parked. As mentioned previously, this type operation was also accomplished by several other amateurs, using similar equipment setups readily available from suppliers of amateur radio equipment.

During March, 1975, after a few months of experience with the then new OSCAR 7, it became apparent that the outstanding signals from the Mode B transponder would provide a new level of performance from a vehicle. The first experiments used a transceiver arrangement as shown in Fig. 3.

The uplink starts with the same regular amateur band transceiver as was previously used for receiving OSCAR 6. This is in the front of the car, so the transmit frequency can be controlled from the driver's seat. A low power output (1 Watt) available from this particular unit is cabled to the trunk, and connected to a transmitting converter (28.150 to 432.15 MHz). This converter

Uplink (at 432.150 MHz)	
Transmitter power x antenna gain = EIRP = 100 Watts	+50 dBm
Free space path loss (at 2000 mile range)	-156 dB
Polarization mismatch (linear on ground, circular at satellite)	-3 dB
Net nominal receiving antenna gain at spacecraft	0 dBi
Received signal at input to spacecraft transponder	-109 dBm
Downlink (at 145.950 MHz)	
Satellite transponder output power (with -109 dBm input signal)	+30 dBm
Net nominal transmitting antenna gain at spacecraft	0 dBi
Free space path loss (at 2000 mile range)	-146 dB
Net nominal automobile receiver antenna gain (including transmission line loss)	+2 dBi
Polarization mismatch (circular at satellite, linear on ground)	-3 dB
Received signal at input to automobile receiver	-117 dBm
Receiver noise (bandwidth = 2.4 kHz, noise figure = 3 dB)	-137 dBm
RECEIVED (S+N)/N	+20 dB

Table 1. Note: At a range of 1000 miles (satellite overhead), the (S+N)/N should be 26 to 30 dB. From these figures it can be seen that very effective communication is possible.

W3TMZ was first QSOed from the car via OSCAR 6. The other cards are from the first few days of operation.

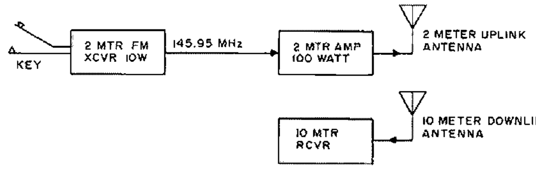


Fig. 2. Simple equipment for vehicular satellite communications.

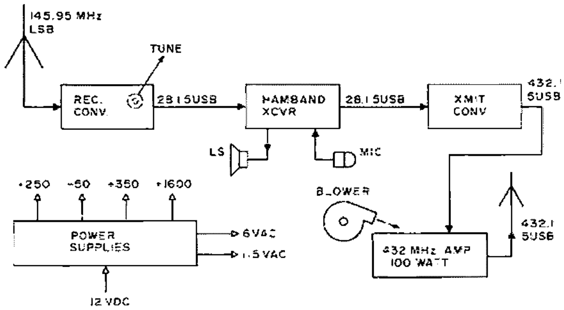

Fig. 3. Transceiver type equipment used in W2GN mobile for SSB communications via OSCAR 7 Mode B.

develops about 3 Watts on the uplink frequency. A stripline tube type power amplifier brings this low power up to the 100 Watt level. A short run of RG-8 cable to a ground plane antenna mounted on top of a standard mobile whip completes the uplink equipment. A rather involved power supply was required to supply all the various voltages required by the tube type uplink equipment in the trunk.

The downlink receiving equipment, since this was to be a transceiver installation, required a special receiving converter to convert the 145.950 MHz passband downlink signals to 28.150 (± 25 kHz) for the transceiver. The crystal in this converter had to be on the high side of the signal to restore the frequency inversion created by the satellite transponder. The crystal also had to be offset to adjust for the small frequency translation irregularity in the satellite transponder and to provide continuous tuning to adjust for the Doppler effect. A crystal tuning capacitor equipped with a vernier dial was employed to facilitate this adjustment. The antenna for the downlink was the same 5/8 wave base-loaded whip previously used for uplink in the OSCAR 6 experiments.

This array of uplink and downlink equipment was tested out thoroughly on the bench by actually communicating via the satellite. The car installation called for a lot of head scratching on equipment location — particularly for the various power supplies.

Murphy must have been looking the other way, because when I finally tried the installation out from my driveway on the first available orbit, I was rewarded with a solid SSB conversation for over ten minutes with W2BXA in New Jersey.

Other than a minor problem in the high voltage power supply, this installation was in troublefree operation for more than two years with impressive results. Particularly on the morning passes, when the 7B transponder was lightly loaded, the return SSB signals were very strong. It was easy to work European stations as well as all of North America and the Caribbean.

Operation in motion is quite practicable with no observable difference from parked. On one occasion, a special test was carried out where the car was kept in continuous motion while the mike was kept continuously active for an entire orbit. The signals from the car were copied by many stations all over the East and Midwest with exceptional clarity. In-motion operation does have a little problem with two-way contacts due to the need for frequent adjustment of the receiver to account for the Doppler shift. One hand on the steering wheel and one on the tuning dial leaves the mike in midair.

A 2 meter sideband transceiver was next installed to supplant the receiving converter described above. This yields the convenience of being able to hear your own downlink signals, an interesting and important aspect of satellite operation. In this setup, the transceiver used to generate the SSB signal on 28.150 was installed in the trunk, taking all the clutter out of the front of the car.

A number of successful demonstrations were conducted at various hamfests and meetings here in the Northeast. The SSB voice signals coming down from the OSCAR 7 Mode B translator invariably gave good loudspeaker copy to large groups by extending an audio line from the car to the meeting hall.

432 MHz SSB transceivers and linear amplifiers became available during 1975, so we continued the equipment saga, and, in early 1976, installed a 432 transceiver alongside the 144 unit in the front of the car and solid state linears for both bands (2m and 70 cm) in the trunk — going whole hog, so to speak.

A regular ham band transceiver plus the usual FM unit provides a capability for all satellite and nearly all regular modes of operation on the ham bands. The antennas continued the same — base-loaded whips on 2m and 70 cm and center-loaded whip for ten meter downlink. We have come a long way in the equipment department since OSCAR 6 was launched in October of 1972. All of the gear mentioned takes up little space in the vehicle. The availability of satellite communications has helped to stimulate this development.

As the AMSAT program for future satellites unfolds, we can expect mobile operation via satellite to be a regular part of the day-to-day ham operation. Continuous coverage via satellite must be held as the ultimate goal, either through use of high altitude satellites or by operating several satellites properly spaced at a lower altitude.

Once that is accomplished, there will be no barrier to communication by amateur radio from any point on the Earth at any time. ■

Tic Tac Touchtone

-- a new method!

Between the looks of the push-button pad arrangement of the Touchtone™ and the hit-and-miss aiming technique I had been running until recently, the title seemed a likely one for the circuit block diagram in Fig. 1. What the circuitry allows you to do is tape record (or manually enter) TT tones that are then entered into a decoder for a one-of-ten number choice. These tones are changed to TTL levels, and from one-of-ten code to BCD. A set of storage latches allows you to enter a six-digit number sequentially, and yet store it as six sets of parallel BCD data. Now, what can you use it for?

As described, I use it to record (or enter manually) azimuth (3 digits) and elevation (3 digits) information on convenient cassette audio tape for a given OSCAR pass. Depending on how you do the recording and playback, you have enough time on one side of a 60-minute cassette to record even the longest 24- to 28-minute pass in real time. At real time, you would start your recording with the starting position coordinates for your antennas, and then enter new information from your calculated data (or Satellabe™) every one-half minute or so, with the tape always running. Two drawbacks! One, this can eat up a lot of tape. Two, it takes as long to record every pass as the pass really takes! I record and play back mine a bit differently. By using a circuit very similar to Fig. 7 (R-S flip-flop wired gates) to control the tape recorder run/stop circuit via the microphone third wire, I waste no tape. You build a second Fig. 7 leaving off Rs, Cs, Rg, Cg, and both switches, since the tape control inputs will be TTL levels. The relay contacts are then wired as in Fig. 7(a) to control the tape recorder run/stop circuit. For inputs to this added IC, refer first to Fig. 2. IC5-11 shows a lead going off to tape. Attach this lead to the new IC pin 13, taking the place of the hold switch of Fig. 7 and forming the tape stop command. Whenever a # is decoded from the tape or direct command, the tape stops. To start the tape, any TTL-compatible pulse from high to low into pin 9 of the new IC will start the tape. The relay will close and the tape will run. To record using this method, let the pulse (from timer or electronic

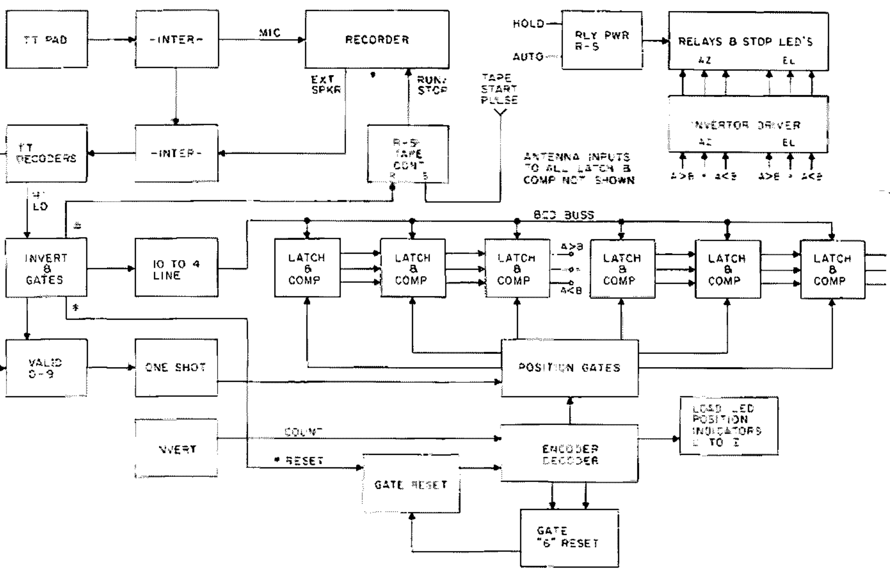

Fig. 1. Block diagram.

clock at 1 or 2 per minute) start the tape on playback, and use a momentary low on pin 9 to start the tape when you are ready to enter new data for a pass when recording. You enter your data in 6-digit format shown by this example for an azimuth heading of 163 degrees and an elevation of 45 degrees: Enter by pushing the TT pad buttons 1, 6, 3, 0, 4, 5, #, for a 163045# sequence. When you hit the # key, the tape will stop, but the tone will be on the tape. Start the tape with a pulse again, and after 2 to 3 seconds, enter the next headings, followed again by #, and so on. When the timer plays back the tape, one 6-digit number and stop tones will be played back for each timer pulse, so be sure to enter data for every minute if a one-per-minute timer is used, or data for every one-half minute if a 2-pulses-per-minute is used, etc.

The interface shown between the TT pad and the recorder is a combination of the TT pad level control, the ALC circuit of the recorder, switches you choose to use, cables and plugs, and so on. Nothing fancy, and not included here due to the many types of pads and recorders. The same goes for the interface shown between the recorder and the TT decoders in the playback mode. It can be any ALC, or the recorder playback volume control, or anything to hold the tone levels to about 50 to 100 mV (if you are using PLL decoders). The TT decoders are also not shown, as they have been in many forms, in many magazines. It's your choice, just as long as the output goes from about +4.5 V dc to ground on the output line when that tone is received.

Taking it from the output of the TT decoders, the high and low tone group outputs (lows) are fed to an inverter so that both high and low are available for each output. Then the inverted forms are fed to gates to decode a single number for any tone pair received. Output from these gates is fed to a 10-line to 4-line converter IC. This 74147 IC happens to accept a low on the 0 to 9 input line side, and outputs $\overline{BCD}$ code equivalents of the digit that was entered. This inversion doesn't bother us, as the $\overline{BCD}$ is inverted again in the 7475 latches by using the $\overline{Q}$ outputs. The then BCD code is fed to a 7485 comparator IC to compare it with the BCD code sent down from the antennas. That covers the signal path, which is really easy. Now for the controlling part!

Going to Fig. 3, all lines that enter each half of IC17 are normally high during no tone. When any valid TT tones are received, one input line of one half of IC17 (pin 1, 2, 4, or 5) and one input line of the other half of IC17 (pin 9, 10, 12, or 13) will go low (for the numbers 0 to 9, but more on that later). Since IC17 is a 7420 4-input NAND gate, all 4 lines of either half input must be high for a low output. When the tones cause these IC17 outputs to go high, IC28-3 goes low. This causes the one-shot IC18 to fire for approximately 5 ms. The one-shot IC18 output enables half of IC19 and IC20, 7408, and gates. The other half of only one of these gates at a time is enabled by what line (U, V, W, X, Y, Z) is also high. If we are in the first digit position, for example, the counter 7490 (IC15) and decoder 7442 (IC14) would be in the zero (reset – 1st digit) position. IC14-1 will be low, and when inverted by IC13-1 to IC13-2, a high results, enabling IC19-3 to a high. This high turns on the latch enable line of IC7-4 and IC7-13. The BCD data for the first digit present on the common BCD bus in Fig. 2 are transferred to the output side of *only* that latch. It is then compared by the 7485 (IC21) with the current antenna BCD read down to the other side of the 7485.

Going back to Fig. 3, the same low for a valid TT tone at IC28-3 that keyed the one-shot IC18 is also fed to IC16-12 and IC16-13, causing a high at IC16-11 and IC15-14. This low to high transition when tones are received does nothing at the counter input IC15-14; however, when the tones stop, the condition reverses (high to low), and the counter advances one position and is ready for the next number. You can follow through the counter (IC15) and decoder (IC14) up through IC14-2 to IC13-1 to IC13-4 to IC19-5, and see that the next position is then half enabled and needs only the one-shot pulse from IC18 when the next tones come along to load the second position latch (IC8) with second digit BCD data.

It should be noted at this time that the TT pad * key can be used to reset the counter and latch positions. IC16-4 and IC16-5 are used in upside-down gate fashion, much like IC28-1 and IC28-2, in that if either high goes away from the inputs, the output goes high and resets the counter. IC16-5 is also used to reset the counter when position "6" is reached in the 7442, so the counter does not rely on the * to reset. The position "6" reset is detected as a BCD 6 by IC16-1 and IC16-2 to IC16-3 to IC15-5.

Referring to Fig. 3 and IC17: The inputs to these gates were originally wired to detect all valid TT pairs, but this leads to both limited and confusing control. By using

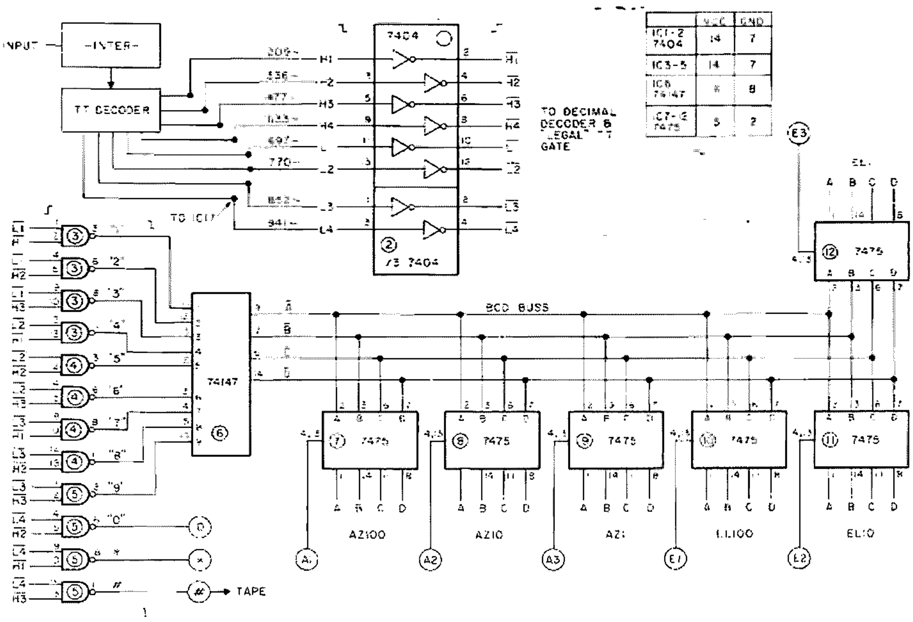

Fig. 2. Decode and store diagram.

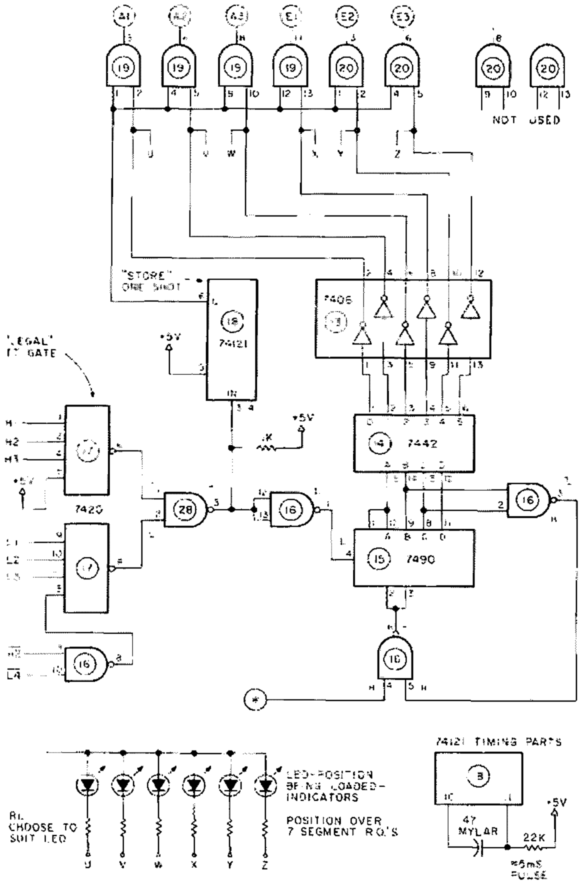

IC #	Name	Vcc	Gnd
13	7406	14	7
14	7442	16	8
15	7490	5	10-6-7
16	7400	14	7
17	7420	14	7
18	74121	14	7
19	7408	14	7
20	7408	14	7

Fig. 3. Control unit.

pin 5 wired to +5 V dc instead of H4 where it was, we delete the decoding of the entire H4 group (A, B, C, and D letters on some TT pads). This allows their detection by NAND gates wired like IC3, 4, and 5, without causing any counter or latch action. After all, you never want to enter this as data to the number latch anyway, but you may want them for tape or local control signals (future use!).

Also, in the low tone group inputs, a gate is added to the L4 input. By doing so, we set up the low tone half of IC17 to only recognize 0 of the L4 group (*, 0, #, D) as a valid number to be loaded into a latch when received. This occurs when the tone pair for zero (H2 and L4) are inverted in IC2 and appear as $\overline{H2}$ at IC16-9 and $\overline{L4}$ at IC16-10 as highs. This causes a low at IC16-8 and a high at IC17-6, and with both outputs of IC17 high, a valid number is "seen" for loading the latch.

Both * and # are L4 tone numbers, but neither has the H2 high tone, so they both are ignored by IC17. Thus, by wiring the IC17 high group correctly, and adding a simple gate to the low tone group, only the numbers 0 to 9 are used to load the latches.

I believe that covers the line by line, so let's examine the 163045 example given earlier, as it progresses through the digital hardware. The 1, of course, was decoded and stored in latch IC7. Then the 6 is put in, decoded, and stored in latch IC8, the 3 is put in latch IC9, the 0 in latch IC10, the 4 in latch IC11, and the 5 in latch IC12. Going to Fig. 4, you can see by the "numbers" shown in ICs 7 through 12 just what is stored where.

If the relay power is in the automatic rotate mode of Fig. 7, IC28, then the antennas will begin to move the instant the first digit is received, decoded, and latched, if it differs from the antenna position in that digit. Fig. 4 also shows the output relay control lines of the 7485s under "other 7485 connections." The 7485 has cascade inputs available at pins 2, 3, and 4, and these pins are used. The overall output of the 7485s seen by IC27, pins 1, 3, and 5 for azimuth, and 9, 11, and 13 for elevation, can be in only one state at a time – either A > B, A = B, or A < B. These overall outputs are in whatever state the 100 IC21 commands until A = B in that IC. IC22 then takes over, followed by IC23 (azimuth example). For instance, if we started the beams mechanically at 000 degrees (north) for azimuth, and 000 degrees elevation, the following would take place after the data was all in and stored (163045), and then the relay power applied with the "auto-rotate" button: IC21 says A > B, output A > B, and the CW relay pulls in to increase degrees azimuth on beams (increase B data) until 100 degrees is reached and IC21 says A = B in this digit. Then IC22 takes over with its own A > B, output A > B, and the CW relay stays in until 160 degrees is reached and IC22 says A = B in that digit. Then IC23 takes over with its own A > B, output A > B, the CW relay stays in until 163 degrees is reached and IC23 says A = B, the azimuth stop LED comes on, and the CW relay drops out.

The same thing happens independently in IC24, IC25, and IC26 for elevation. In our example, IC24 immediately sees an A = B (0 = 0) and transfers control to IC25 until 40 degrees elevation is reached and an A = B condition is reached in IC25. Then IC26 takes over with an A > B command until 45 degrees is reached when the up relay (energized until now and driving the beams upward) drops out and the elevation stop LED light comes on. The system is then at rest, and remains so until further data streams are received from the tape-timer or by manual entry.

While on the subject of the relays, Fig. 7 was added so that data commands could be entered when in the hold (no relay power) mode without actually turning on the antennas. It is a handy override, because if you want to stop the antennas at any time, you can do so with a push on the "hold" button. Hitting the "auto-rotate" button returns control to the latches of the TT controller system. This also means that you can cancel a taped command by overriding it with the hold button, enter a manual command, and return to automatic by pushing the auto-rotate button.

I included a panel layout (Fig. 6) to give you a starting point. Laid out this way, it is functional and not confusing. I used orange plexiglas over the BEAM 7 segment displays, and ruby red in front of the DATA entered readouts to avoid mix-ups. The hold LED is red, the auto-rotate green, and (in my case) the CW, CCW, Dn, and Up LEDs are all yellow. The az and el stop LEDs are, of course, red. The panel is gray, with black TT keys with white lettering, so it makes a nice addition to my Drake equipment. In fact, I used a Drake speaker cabinet (MS-4) and had tons of room left over, both on the panel and

in the box.

This system replaces the earlier Autotrak* at my QTH, but to each his own. If you have the RTTY gear, the earlier system was okay, but required a lot of hardware to get from Baudot to BCD and the like just to have the advantage of pre-stored tape (paper tape in that case). The advantages of this newer system override any drawbacks of not having a hard copy printout, and careful labeling of the cassettes should eliminate any problems.

With the average OSCAR antenna setup, having tapes for every 5 degrees of longitude seems to be more than adequate, amounting to some 15 to 20 pass combinations, worst case. All this fits nicely on 2 cassettes in my non-real time system. You can get sneaky as you record by using a pass "code" information right on the tapes. Let me show you by example. Since azimuth information is the closest to longitude or surface information, I chose to use those readouts to locate a point on a tape containing some 4 to 6 passes. When recording, ahead of each sequence of pass information enter the following "code":

*"Introducing Autotrak!", W9CGI, *73*, July, 1977.

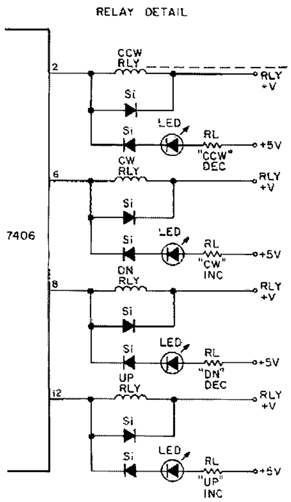

Fig. 5. Si = silicon diode, 50 V, 100 mA. All RL chosen for LED used.

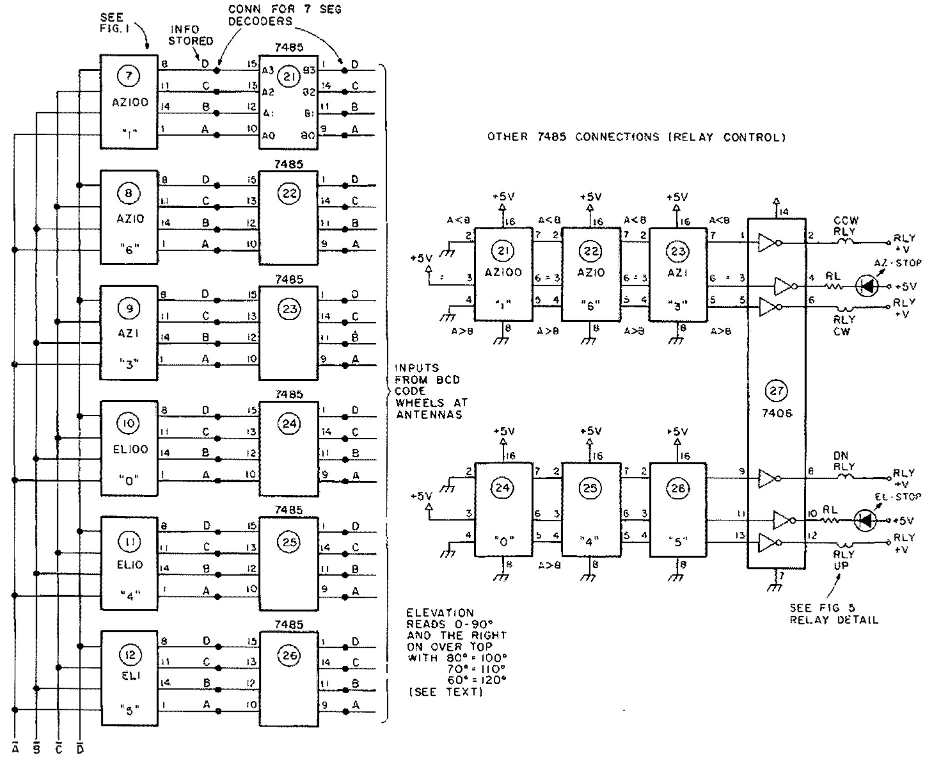

Fig. 4. TT controller.

Push *, then whichever of the A through D keys you want to use for this function, then the longitude of the equator crossing for that pass you are about to enter next as a 3 digit number, then 0, then 0, then 0, then the A to D key you chose above again, then wait 10 seconds, then push the * key to clear the register (counter), then wait 5 seconds, then begin entering your data for the pass as shown before.

By opening the antenna circuit with the hold key, and defeating the tape stop command by closing the defeat switch in Fig. 7, you can go down about 30 minutes ahead of the pass. While letting the gear warm up (*please!*), you begin playing the proper tape back. Example: An overhead pass for me is 72 degrees crossing at the equator, so I take my 52 degree to 77 degree tape (I go in 5 degree increments on either side of an overhead pass here) and put it on the recorder. The pass I am looking for is the fifth one on this tape. When the tape begins playing back, the first information I get is a *, to clear the counter to position one regardless of where it came on when power was applied. Then the D tone is in my case decoded and wired into an audio monitor (NE555s and a speaker) to form a 1000 Hz warning tone that in this case means that longitude information is about to be presented on the data readouts. Next, the tape decodes and displays the digits 052 000 on the data readouts, telling me that the information that follows is for a pass having a 52 degree equator crossing. The audio warning is repeated. Then the decoded * clears the data counter to the 1st position (it should be there due to a detected 6th digit position after the last 0 was entered — but why risk it?). The information that follows is pass data, and the # does not shut off the tape, since you defeated that circuit. When the tape reaches the next "code" information, the above is repeated (in my case: clear, tone, 057000, tone, clear), so that you stop the tape manually right after the equator crossing you want (072000). You would then push the defeat switch to normal and the auto-rotate button, and set up your timer to control tape starts. For the exact time of the crossing, I

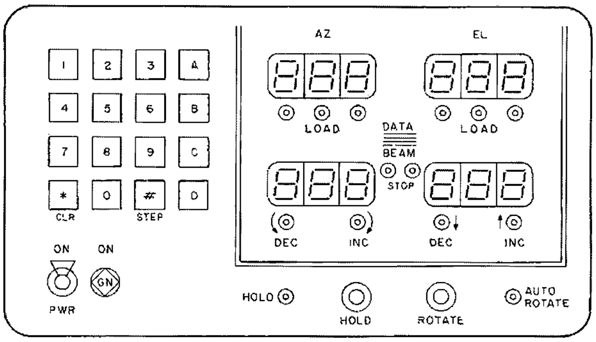

Fig. 6.

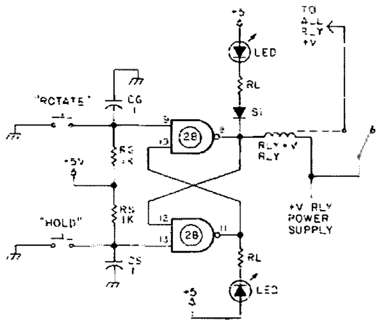

Fig. 7(a).

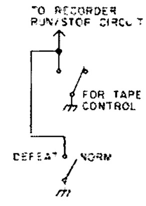

Fig. 7(b).

enter the approximate azimuth from the Satellabe™, and an elevation of 000 degrees. Two reasons: One, I can start all runs with the published crossing time, even though the satellite is out of range — it is not always out of range! Two, this gets the antennas into approximate position for your AOS position anyway, so you don't have to wait on them coming around. I use an automatic call sender that keys off the same high to low transition from the timer that starts the tape, so I listen for myself even before normal AOS and then turn off the sender. This all makes every pass a very repeatable situation — they all start at the equator, and the first tape information is for equator plus 30 seconds. I run the beams around to the equator start point with a manual entry from the keyboard, just before doing the timer setup. This way, I have *one* manual function to do concerning the antennas when the satellite crosses the equator — pushing the "go" button on the timer to start the first thirty second period. Thirty seconds later, the timer sends a pulse to the controller — tape start — and the T + 30 data is read in and the beams run to that position. At 40 degrees latitude, this is always the same as what you manually loaded, so you could include it on the tape and let the tape read in the initial condition by turning the normal defeat switch from defeat to normal (*after* the longitude figures you want are read and clear themselves, but *before* the first data coordinates are picked up off the tape — we left about 5 seconds). This way, the decoder picks up the first tape stop #, and would wait there until the timer T + 30 pulse — putting you right back in sync.

That sums up the theory and the how-to-tape information part. It works great, and allows me to concentrate on the receiver instead of growing a third hand for the antennas. No doubt you will find your own uses and probably some variations, and that's good — write them up! I have no beef with anyone who starts with my idea and improves on it — chances are I'll add it to my system, too.

Please include an SASE if you need help. The letter load has increased with the increase in my "articles published" count, but same day answers are usually still possible if you make your questions clear and concise. Adaptations and modifications by you take a while longer, since I like to try what you did on the hardware here and see what really happens. ■

LETTERS

from page 16

of '76. In January '77, I flunked my first time on the General, but then went in February and passed it. Then 3 months later (May), I passed my Advanced; 2 weeks later in June, and during the last week of school, with all the final exams, yea, I walked away with the Extra on my first try. Same day I sent away for my 1 x 2 call. Youngest ham to get (or have) a 1 x 2 call?

I guess if you show this letter to some of your local CBers, it'll get 'em off their tails and show 'em how easy it is.

How did I do it? Naw, I'm not a "child prodigy" and my marks in school aren't too good. It took a lot of time and energy and staying away from all the wild women. And if you wanna speak to me, I'll probably be on the bottom of 20 meters CW (or where I am now, relegated to 2 meter FM with a borrowed HT because of antenna problems). And I'll talk to anyone.

PLUGGED IN

Right on, Mark Clark WB4CSK, "Letters," September issue of *73!*

Through studying and a conscientious effort, I earned my license (Advanced). Because of that, I have a certain sense of accomplishment and pride in being part of the fraternity of ham radio. Also, because of that, I would not knowingly do anything to jeopardize its existence.

For those who subscribe to the quantity theorem for getting newcomers into ham radio, I propose that you listen to Ch. 19 CB for a couple of days, then ask yourself, "Do I want to listen to that on the ham bands?" There are too many appliance operators in our ranks as it is now.

For those existing amateurs who believe in easier upgrade privileges, take another look. Maybe you are one of those appliance operators.

Richard L. Miller WA4OET
Ft. Belvoir VA

UPDATE

We were indeed happy to see your three-page coverage of TEN-TEC modifications to the Argonaut in the August, 1977, issue of *73*. The only problem that we see is that it was not pointed out anywhere in the article that the modifications described were performed on our old Model 505 Argonaut, which was replaced in June of 1975 with the Model 509. The Model 509 indeed incorporates the modifications shown in the article with the exception of the disconnect socket on the speaker. The reverse polarity protection and the drive control on the front panel are incorporated in the Model 509 and always have been. I would appreciate it if you would run this information in your letters column so that owners of the Model 509 do not feel that modifications are desired or necessary with their units.

The only statement in the article that we take exception to is the one where it is intimated that TEN-TEC had a prepackaged kit of parts for repairs to units that were connected up reverse polarity. I know of no such prepackaged kit, but the usual damage was to the switching transistors on the control board, and possibly the large electrolytic capacitor across the dc line.

TEN-TEC, Inc.

Visual OSCAR Finder

-- nice side effects!

A very unique OSCAR-locating aid appeared in *QST* in May, 1974, described by WØCY. It consisted of a rotating globe with several LEDs around it, sequentially turning on and off to simulate the position of OSCAR. The project used several gearing arrangements, entirely too many LEDs, and a 115-position rotary switch to accomplish its task. I felt this to be too costly and mechanically complicated, and I was prompted to simplify this otherwise excellent article.

Completed OSCAR finder.

The only mechanical device in my locator is a 24-hour clock movement, obtained from a Master Crafters 24-hour world clock. This clock was popular with hams in the 1960s and can be found at hamfest flea markets. Mine had been retired years ago, when I built a digital station clock. The movement and all hands are removed from the clock, and the back cover is removed from the movement to expose the gears. For this project, it is necessary to reverse the rotation of the clock. The motor will go in any direction in which it is started, but there is a ratchet underneath the only yellow nylon gear in the movement that forces the clock to turn clockwise. This ratchet is removed by drilling out the rivet holding it. Now the clock will turn in any direction in which it is started.

The globe used was bought in a five-and-ten-cent store, and it is made by the Ohio Art Co. It was originally intended to be a bank, so the base on it must be removed. This is easily accomplished by pulling the base straight out from the globe. Next, a ¼" hole is drilled in the south pole, and the outer ring, salvaged from the hour hand, is soldered to the globe at the south pole, after removing the paint from the globe and the ring at the point of attachment. The globe will now fit snugly on the outer shaft of the movement, as the hour hand did. On the globe, a 2500-mile-radius circle, drawn to scale, is centered around your QTH and drawn with a marking pen. This indicates the area within

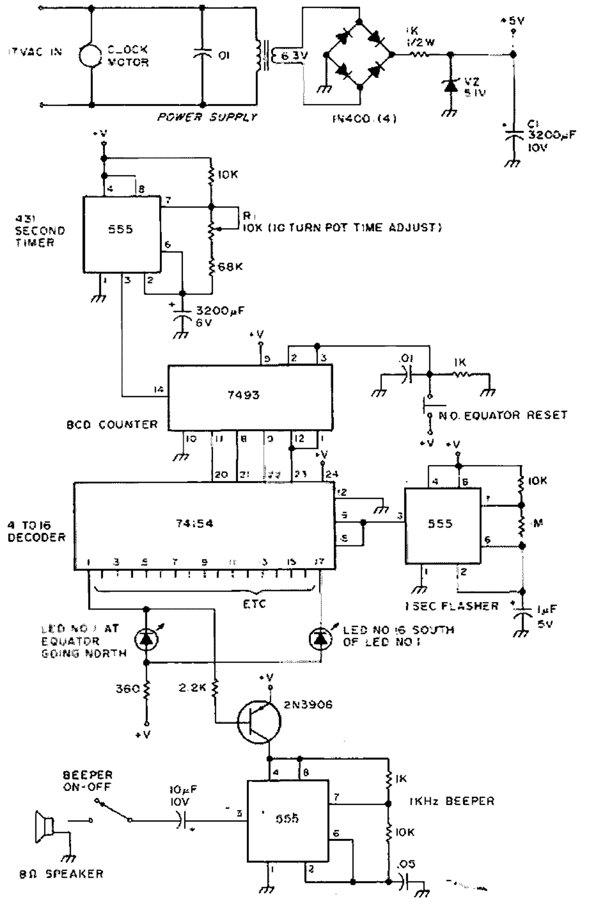

Fig. 1.

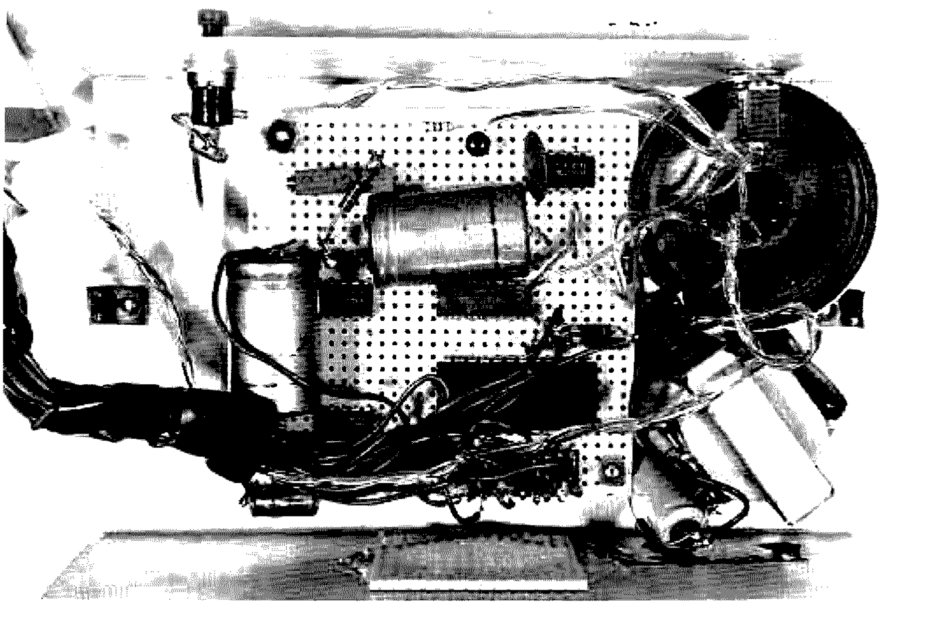
which the satellite may be worked.

The 16 LEDs are soldered to a piece of bus wire shaped in a 5" diameter ring, to simulate the satellite's orbit. Separate wires are run from the cathodes to the appropriate pin on the 74154 chip. Small pieces of plastic tubing are used between the LEDs, covering the bus wire and connecting wires. The LEDs are spaced so that one is placed at each of the poles and at the equator on both sides, and three are evenly spaced between each of these. The ring is held to the cabinet with a cable clamp and adjusted to an angle of 102 degrees for the OSCAR 6 orbit.

A 555 timer chip is connected for astable operation with a period of 431 seconds (114.9946 min./16). The exact time is set by adjusting the 10k 10-turn pot, which is in series with the 68k resistor. The output from this clock goes to the input of a 7493 BCD counter. This device gives the appropriate 4-bit BCD code for the number of transitions that occur on pin 14. After reaching 16 counts, the counter resets to the 0000 state. There is also provision for externally resetting the counter for setting the device up initially.

The four lines from the 7493 drive the inputs of a 74154 4-to-16-line decoder. This device has four lines in and sixteen lines out. All outputs except one are normally high. The output that



Suggested parts placement for OSCAR finder

PC boards are available from the author for
$6.00 plus $1.00 for postage and handling.

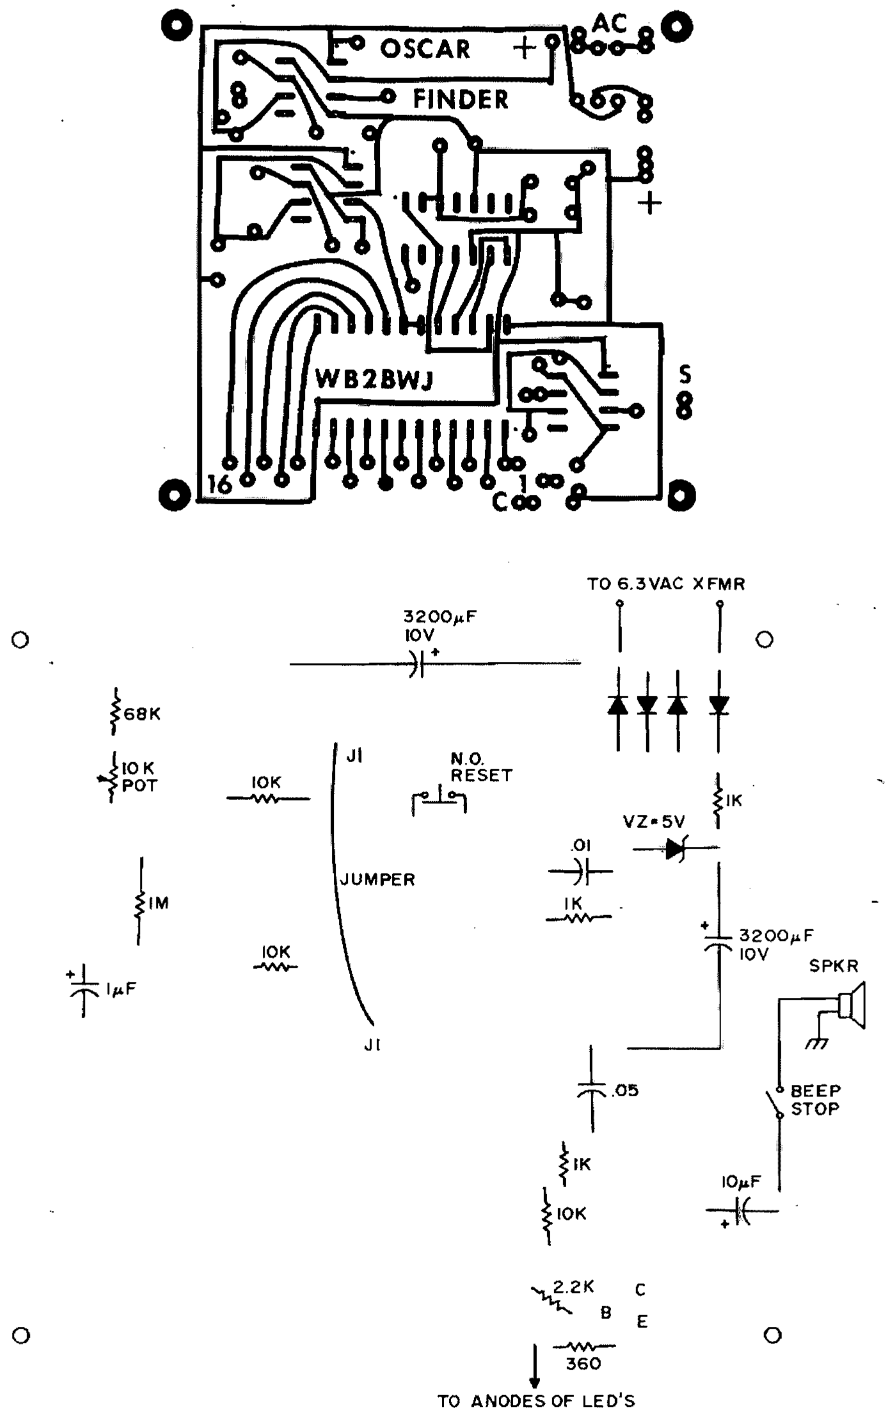


Fig. 2. PC board.

goes low is the one whose BCD code has been addressed at the input. For example, if the four lines in are 1010, the tenth output goes low (pin 11). These output lines directly drive the appropriate LEDs through a current-limiting resistor.

LED number one is placed at the equator going north, and the other LEDs follow it sequentially. To make the LEDs more visible, they are made to blink on and off. This is done by driving the strobe inputs of the 74154 with another 555 astable set at about 1 Hz. When LED number one comes on, it turns the 2N3906 transistor on, which, in turn, activates a third 555 astable which oscillates at about 1 kHz. This chip drives a small 8-Ohm speaker, when the LED at the equator is on, with a beeping tone. This alerts the operator that the satellite is entering the Northern Hemisphere. A switch is provided to turn the beeper off, if it becomes annoying.

The power supply is conventional and adequate, and it should be noted that one does not really need a 3200 uF filter capacitor. I used it because I had an extra one in the junk box. Use one large enough to give a clean tone, free from hum, in the loudspeaker.

I found the accuracy of the 555 timer used as a clock entirely adequate. However, greater accuracy can be obtained by using a smaller capacitor of the tantalum or polycarbonate variety and using a larger value precision resistor. This might buy some thermal accuracy, but, within the box, we find a thermal equilibrium, due to the heat produced by the clock motor, transformer, and chips. As long as the shack's temperature doesn't change too drastically, the clock averages quite well. For the real perfectionist, I suggest a crystal oscillator with an appropriate divider chain.

To align the unit, the 10k pot must first be set so that the period of the clock astable is 431 seconds. This is a somewhat lengthy process, but it must be done as accurately as possible to insure correct tracking of the satellite. Allow the unit to thermally stabilize itself before finalizing the adjust-

ment.

To set the satellite's position, the following should be done. Use an OSCAR locator or similar device to determine an equator crossing on the day that you are setting the OSCAR finder. Determine the local time of the crossing and the degrees of longitude. Remove the globe, and observe if the second-hand shaft is turning counterclockwise. If it isn't, take a pair of needle-nose pliers and force the shaft to turn counterclockwise. Replace the globe, and set the globe by turning the time-setting knob until the number one LED is at the correct crossing point on the equator. This globe is marked at every 15 degrees of longitude, so it is easy to estimate the correct point. Press the zero-degree start button, and wait until the beeping stops. At this instant, press the reset button again. This will insure that a complete cycle is started. Readjust the globe so that the LED lines up with the crossing point. One must use good timing to insure that this process can be completed by the time that the pass is to occur.

Periodically check the accuracy of the OSCAR finder with an OSCAR locator or similar device, and recalibrate it by turning the globe, if necessary.

Whenever an LED appears within the circle on the globe, OSCAR is within range. Although designed for OSCAR 6, the OSCAR finder can be used with any satellite by adjusting three things: angle of orbit, period of orbit, and radius of circle on globe, which is related to the altitude of orbit, which is related to the period. Finally, any 24-hour movement or globe that is available can be used, and most of the other parts are readily available, as listed in the parts list, from local stores as well as from the mail-order houses. Good luck on OSCAR hunting! ■

Before the
FEDERAL COMMUNICATIONS COMMISSION
Washington, D.C. 20554

In the matter of

Dismissal of six Petitions for Rulemaking in the Amateur Radio Service

RM-1455, RM-1536, RM-1703, RM-2080, RM-2797, RM-2907

ORDER
Adopted: August 24, 1977
Released: August 26, 1977

1. The Commission, by its Chief, Safety and Special Radio Services Bureau, acting under delegated authority, has under consideration the six petitions for rulemaking listed above, each of which was submitted in accordance with the Administrative Procedure Act, 5 USC 553(e), and Section 1.401 of the Commission's Rules. The petitions we are considering each request certain changes in the Commission's rules or policies governing the assignment of station callsigns in the Amateur Radio Service. Petitioners' specific requests are as follows:

a. *RM-1455.* Mr. Wayne Green requests amendment of Section 97.53 of the Rules to permit a licensee moving from one callsign area to another to obtain a "counterpart" callsign upon modification of his station license. (A "counterpart" callsign is a callsign with a suffix identical to the suffix of a callsign held in another callsign area.)

b. *RM-1536.* The American Radio Relay League, Incorporated (ARRL), also requests that provisions be made in the rules for the issuance of "counterpart" callsigns.

c. *RM-1703.* Mr. Thomas V. Appler asks for revision of Section 97.51 of the Rules to permit the assignment of a specific unassigned callsign to the widow, son, or daughter of a deceased former holder of that specific callsign.

d. *RM-2080.* Mr. Chester L. Smith, Mr. Joseph Santangelo, Mr. Charles A. Walbridge, and Mr. Donald A. Freeland want the Commission to amend its rules to permit the issuance of callsigns containing a special indicator designating the operator license classification of the station licensee.

e. *RM-2797.* Mr. Cliff Ryan requests that the Commission issue station callsigns with a special designator to indicate the state in which the station is located.

f. *RM-2907.* Mr. Robert E. Babb requests the rules be amended to permit the issuance of so-called "one letter" callsigns in the Amateur Service. (A "one letter" callsign is a callsign consisting of one letter, followed by one number, followed by one letter.)

2. We have fully and carefully analyzed petitioners' requests and have concluded that petitioners' proposals have been and are being considered in connection with other rulemaking proceedings. With respect to each of these petitions, we note that in Docket 21135, Notice of Proposed Rulemaking released March 11, 1977, 42 Fed. Reg. 15438 (1977), the Commission proposed to simplify its amateur station callsign regulations by replacing the existing complex rules with a very simple general rule stating that all callsigns shall be assigned by the Commission on a systematic basis. The Commission's proposals in Docket 21135 would, if adopted, preclude granting any of the petitions under consideration, each of which requests the issuance of special format, non-systematically assigned callsigns. In connection with RM-1703, we would also note that the Commission explicitly considered the question of "in memoriam" callsigns in its First Report and Order in Docket 20092, FCC 76-348, released April 22, 1976. In that Report and Order, the Commission eliminated the availability of "in memoriam" callsigns. (Such callsigns had previously been available to qualified amateur clubs and organizations.) Finally, we would observe that the suggestions contained in RM-2080 were considered, and rejected, in Docket 15928, Report and Order adopted August 24, 1967, FCC 67-978.

3. From the foregoing, it is clear that the factors on which petitioners' proposals are based have been and are being fully considered by the Commission in connection with other rulemaking proceedings. Further, petitioners have not advanced any new or novel arguments warranting additional consideration.

4. Accordingly, the Commission ORDERS, by its Chief, Safety and Special Radio Services Bureau, acting under authority delegated to him by Section 0.331 of the Commission's Rules, that RM-1455, RM-1536, RM-1703, RM-2080, RM-2797, and RM-2907 ARE DISMISSED.

Charles A. Higginbotham
Chief, Safety and Special
Radio Services Bureau

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz. OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz. Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

Cheap Ears For OSCAR

-- an effective satellite antenna

Have you been thinking about trying to work through OSCAR 6 or OSCAR 7? How about even just listening to it? You can perform a valuable service to amateur radio, especially now, if all you do is listen! The OSCAR beacon frequencies on the downlink provide AMSAT with much valuable data on the satellite's health and well-being, and, at the time of this writing, we have an ailing bird up there. Even though by the time you read this the problem may be cured, it has happened before, and we all can help ourselves and AMSAT by listening to and forwarding the telemetry information to them.

This brings us to the need for a 10 meter antenna for receiving the downlink activities. The antenna described in this article will do a fine job for you for a minimum of cash outlay, and it has a few distinctive advantages over even the full-sized beam placed outdoors. First, you do all the aiming and rotating electrically and without rotors. Second, it has the advantage of being indoors in the attic. The second point is nice because there will be no weather wear and tear. It's also nice if you live in a neighborhood that objects to large outdoor antennas because of their appearance and their potential for causing TVI, RFI, etc.

This antenna is only a group of dipoles. Many stations use only a simple dipole or folded dipole for OSCAR, and that is where I began. Once I tried that, I began to wonder what I could do to rotate it to allow for azimuth heading changes (a rotor?) and how to account for polarization shifts as OSCAR tumbles. You may find, as I did, that the polarization makes the mechanical rotation a physical beast, if not impossible to control.

About the time I discovered that, I had been reading an article on electronically steered antennas for the military. Between their thoughts for the initial idea and the physical limitations of my attic, I came up with the following indoor antenna that beats everything I've ever tried outdoors, including a 3 element yagi. I'm sure in the latter case it was a matter of unwieldy steering and not lack of gain.

The antenna is a combination of 4 dipoles, 2 phasing lines, and 3 relays – nothing more. The main reason it works so well is the almost perfect repeatability of the OSCAR pass for any given longitude equator crossing.

Two of the dipoles lie horizontal, or parallel to the attic floor, are oriented east and west at the ends, and are ½ wavelength apart. The other two dipoles are a bit harder to explain. Half of each of them looks like a continuation of the phasing harness running north and south, respectively, on each end where the phasing lines join the first pair of dipoles. The other half of the second pair of dipoles extends straight up, or vertical to the phasing lines/dipole connecting points, or as close to vertical as your roof allows. Mine slope inward toward the center feedpoint (and each other) at an angle of 30 degrees off vertical. Looking at half of the antenna from the east end of my attic, so you are looking west with your eye at floor level, gives you Fig. 1. You are looking at the south half of the array, and the backward "L" is one dipole. The box represents relay 2, and the circle is the other half of the south end pair of dipoles. It extends straight out of the page, half toward you, and half out of the back of the page away from you. Fig. 2 is the view of the north half of the array, viewed from the same place (east of the antenna, looking west, at floor level). The dotted lines in both figures are the vertical portion of the dipoles, which I had to slant toward each other because of my roofline.

Fig. 3 describes how the relays are wired to the antenna to allow changes in pattern (or, in other words, steering). To describe which antenna goes where electrically on the relays, I use the following terminology. The dipoles that lie horizontal and parallel to the floor I call north A and south A. The dipoles that have half of themselves vertical or perpendicular to the floor (or slanted as your roof allows) are north B and south B.

I haven't gone into just what pattern results from what, but I can tell you what the relays are doing as far as the antenna feed. Relay 1 lets

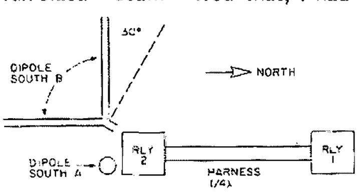

Fig. 1. Looking into the page, you are looking west.

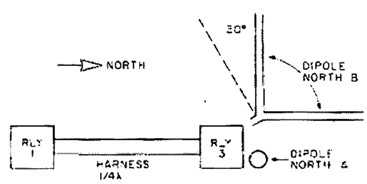

Fig. 2. Looking into the page, you are looking west.

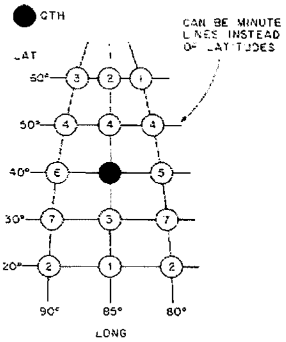

Fig. 4.

you feed the north end pair 180 degrees out of phase from the south end. Relay 2 lets you change the feed phase 180 degrees on south B. Relay 3 lets you change the feed phase 180 degrees on north B. You antenna engineers can drop me a line on just what antenna patterns are supposed to be occurring. I seem to be getting more than the circle of coverage would indicate I should, allowing complete passes of beacon coverage. The beacon is the best indicator, since it does not rely on the other station properly aiming his 2 meter antenna.

Speaking of the circle of coverage you have all seen on maps used for OSCAR tracking, mine now has a slightly different look. It is a grid with small circles at the intersections as shown in part in Fig. 4. The numbers represent the best antenna switch position for the satellite when it is over that map point. After a few runs, and if you determine where the satellite should be by using a Satellabe or equal device, you can find the satellite and form your own chart. You can immediately see there are more than three numbers, representing more than the three individual relays. Fig. 5 shows how I have mine wired to have the following relay combinations: none, 1 only, 2 only, 3 only, 1 and 2, 1 and 3, 2 and 3, and all (energized).

Since I had automated control in mind from the beginning, I wired my relays and switch as in Fig. 6. By using a BCD output decimal display switch, you can choose any of the positions 0 to 7 for any relay combination. Once you learn what position you want and where and when, the BCD switch can become a tape input that is stepped with time during the pass of OSCAR.

I did say automated, didn't I? Well, the tape was good, but the latest adventure seems to be the greatest of all ways! By hooking a 7490 encoder to the 7445 inputs instead of the BCD switch or tape, and driving the 7490 clock input with a variable square wave from a pot controlled VCO (LM 566, etc.), you have much what the military has for a steered antenna for radar, which scans the horizontal plane for targets!

So far I have been limited by the switch speed of the relays in my system, and weather (no heat in attic) has prevented their change to a diode steering scheme. Now come spring . . . hmmm? Since the antenna never handles transmitter type power levels, diodes should be a cinch. If the ideal sampling rate can be found, the antenna will be looking where it should for a long enough time to reproduce enough segments of good audio to sound like it is not switching at all. I believe this to be a rate well above the audio frequencies I can use on the relays, limited only by the ICs (20 MHz?), the diodes, and the other components. Someday I may be able to reduce the total feedline to the attic to just that — the coaxial feedline, running rf power filtered for the switch rate down, and all the switching up.

My first idea was to tie 8 op amps to the agc line of the receiver via some gates to gate them on with the sample switch. Then I would use a voting system to return to the highest agc reading on a sample for .1 second and go back and hold for .9 seconds basis (or 1/sec sampling). If the agc were audio derived and a noise blanker was used, this may still be the best bet. At the very least, this whole thing offers some really nice possibilities. You could use "chain gang" methods of

Switch position	Relays energized
0	none
1	relay 1
2	relay 2
3	relay 3
4	relays 1 and 2
5	relays 1 and 3
6	relays 2 and 3
7	all relays

Fig. 5.

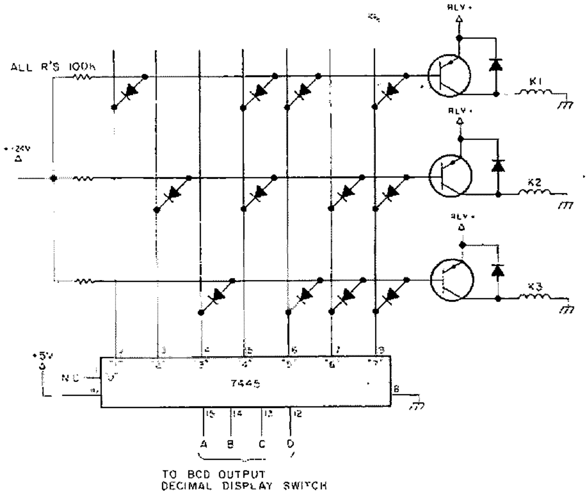

Fig. 6.

7490 connections as blocked out in Fig. 7.

The vco runs the 7490 (B) at antenna switch rate. For the 1 out of 10 sample period, 7490 (C) divides the antenna rate by 10 and only enables the gate ahead of 7490(A) during 1 of 10 periods (1/10 of a total sample to sample period). Position "8" of 7490 (A) and 7445 (A) can be used to do the settling and voting time (half enable a gate, etc.); position "9" would then switch the antenna to that best antenna position decided on in the voting process. A 9 sample period's length of time from 7490 (C) and 7445 (B) later [for example, 7445 (B) positions "0" and "2" through "9"], the process would repeat by 7445 (B) returning to "1" and gating on gate (A). I have tried to block diagram only one of several possibilities. Let your imagination be your guide, as the real intent of this article was the antenna itself.

The antenna (dipoles and harness) is made of inexpensive TV receiver type 300 Ohm twinlead. Since all four dipoles are hooked up all the time (one configuration or another), the north pair in parallel represent about a 150 Ohm feedpoint. The same holds for the south pair. By using a ¼ wavelength harness from relay 1 to relay 2 common poles and relay 1 to relay 3 common poles, the feed looking into each harness from the relay 1 end is about 300 Ohms. When the harnesses are put in parallel by relay 1, the feedline input point looks like about 150 Ohms. Even though it is a mismatch, I attached a 75 Ohm unbalanced (coax) to 300 Ohm balanced balun to this feedpoint with no adverse results. This allows me to use the 75 Ohm RG-59 coaxial cable down the 30 odd feet to the basement and the receiver. I probably make up most of the balun loss, and then some, by running a pretty hot VHF Engineering preamp ahead of the receiver.

As stated before, any ideas on how it works would really be appreciated, and any questions — just SASE. Happy OSCAR times to you. ■

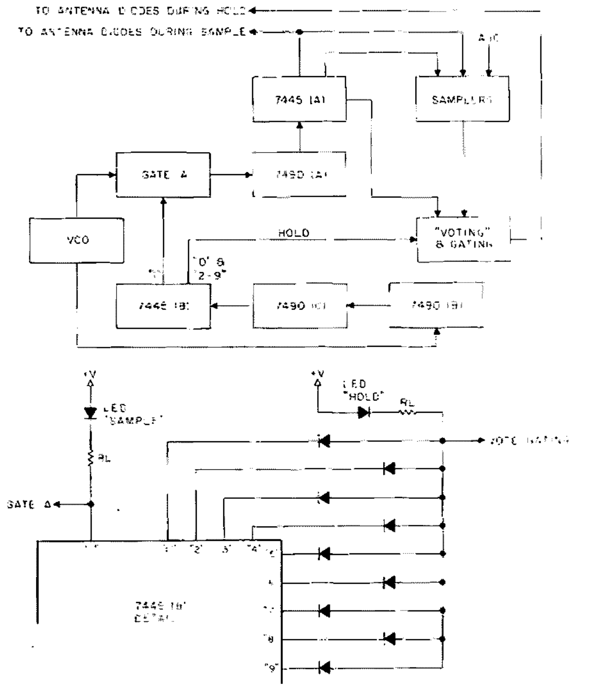

Fig. 7. Voting system.

Track OSCAR With Your SR-52

-- requires the PC 100 option

Art Burke W6UIX
4011 College Avenue
San Diego CA 92115

The program listed in Table 1 will do the following for you, while you QSO, have breakfast, mow the lawn, go shopping, etc.: (1) calculate the position of OSCAR 6 or 7 at the time intervals you select; (2) determine whether OSCAR is above the horizon; (3) print out the time (local or GMT) to the minute, azimuth (bearing), and elevation angle to the nearest degree only when OSCAR is above the horizon; (4) do the above for all the passes (northbound and southbound) for an entire day (longer, if desired); and, finally, (5) do this wherever you are in the world.

Item 5 is especially important for those hams operating near the equator or in the Southern Hemisphere. The usual formulas give erroneous azimuth pointing angles when OSCAR is south of the equator. Formula 3 (see below) corrects for this condition. Additional features are that your QTH is stored in registers 98 and 99 (unaffected by "clear memories"), and all OSCAR orbit data is stored in the upper data registers (15-19), so the calculator can be used for other problems without disturbing the OSCAR data.

Let's examine item 5 in more detail. Fig. 1 shows the actual OSCAR track (solid line) for the example given later where OSCAR crosses the equator northbound at 78.1° West, and the apparent track in the Southern Hemisphere (dotted line) of the track for the preceding orbit which results in the 78.1° crossing. The usual formulas (which are good only in the Northern Hemisphere) will make OSCAR apparently change course as soon as it crosses the equator. Thus, instead of continuing in a southwesterly direction after crossing the equator at 243.7° W., OSCAR apparently abruptly turns southeasterly, as shown by the dotted line, and ultimately crosses the equator in a northeasterly direction at 78.1° W., and then abruptly turns and proceeds in the correct northwesterly direction. Of course, OSCAR doesn't really do these acrobatics, but formulas 1 and 2, as usually given,[1] which calculate the latitude and longitude of OSCAR at the selected time intervals, give these apparent positions. And, since these positions are used in conjunction with our own positions on Earth (latitude and longitude of our QTH) to calculate the direction to point our antenna at OSCAR, we will be wrong!

Well, if this is really so, why haven't we hams in the United States noticed this before? Why do the formulas seem to work okay for us? The answer is that we are so far from the equator, and our antennas have broad enough beamwidths (approximately 40° wide at the "3 dB down" points for a so-called 13 dB beam), that the apparent "dogleg" in the path is entirely contained within our beam coverage and goes unnoticed. I have shown a 40° beam pointed from Miami toward the 78.1° W. crossing in Fig. 1. Notice how it encompasses both the true and apparent paths of OSCAR within the "OSCAR horizon" of Miami, shown as the dotted arc centered on Miami. And, of course, the effect is diminished as we are even further north, because OSCAR is in range below the equator for a shorter distance (or not at all), and the antenna beam covers a large area below the equator.

Now let's take a ham in Quito, Equador, whose QTH is at 0.2° S. latitude and 78.5° W. longitude. He is really in trouble if he uses formulas 1 and 2. His calculator will tell him to point his antenna in a southwesterly direction to

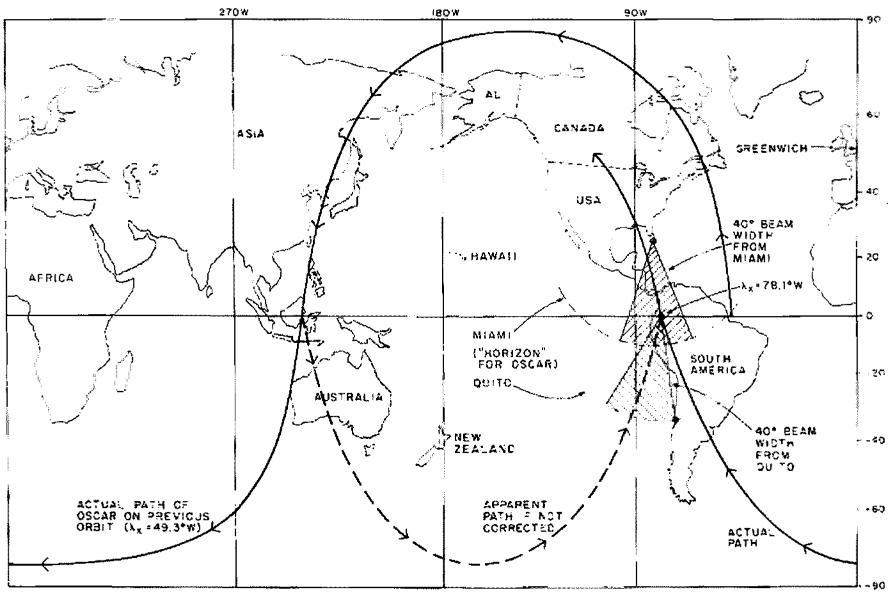

Fig. 1. OSCAR paths, actual and apparent, on the Earth.

pick up the approaching OSCAR, instead of the correct southeasterly direction. Although his antenna may be 40° wide, it is not wide enough to include the direction of OSCAR, as shown by Fig. 1.

In even worse shape would be a ham in New Zealand, for example. The apparent path of OSCAR is south of him, heading east, when in reality it is clear around the world below South Africa.

The part of equation 2 that causes this trouble is the first portion in the brackets:

$$[\mathrm{INV}\cos(\cos\frac{360t}{P}/\cos L_s)]$$

When OSCAR is in the Northern Hemisphere, but approaching the equator, it is a trifle less than ½ P, since it is the time since OSCAR crossed the equator going north, and P is the time of the full orbit. Thus 360t/P will be less than 180 (let's say 176.9, for example). The cosine of 176.9° is -.99854. L_s, the latitude of OSCAR from equation 1, is about 3°; its cosine is .99863. The result is the inverse cosine of -.99991 or 179.2°. Now, let the OSCAR go an equal distance past the equator so that 360t/P is 183.1°. The calculator computes the cosine as -.99854 (the same as for 176.9); the latitude is now about 3° S. or -3°, whose cosine is .99863 (the same as for 3°). The result is that the calculator give you the same inverse cosine of -.99991 = 179.2° as before. After all, how can the calculator know that you want an answer greater than 180°? Thus, the OSCAR seems to be backtracking in an easterly direction as it heads south, and gives the apparent track as shown in Fig. 1.

The answer to this problem is simple: If the latitude of OSCAR is positive (north of equator), use the equation as is; if the latitude is negative, subtract the angle obtained from the bracket from 360° (e.g., 360 - 179.2 = 180.8), and use that value of longitude in the subsequent calculations. (In the program listed in Table 1, I have done the equivalent by testing the sign of the sine of L_s to save program steps.)

For those hams with an interest in how and why things work (most of us, I think), here are the formulas used and a brief explanation of their place in the program. 1 and 2 are adapted from reference 1; the other expressions are from reference 2.

1. $L_s = \mathrm{INV}\sin(\sin a \sin\frac{360t}{P})$
2. $\lambda_s = [\mathrm{INV}\cos(\cos\frac{360t}{P}/\cos L_s)] + \lambda_x + t(15)$
3. If $\sin L_s$ is positive, λ_s is as given by 2. If $\sin L_s$ is not positive, $\lambda_s = 360 - [\ \ ] + \lambda_x + t(15)$
4. $v = \lambda_s - \lambda_q$
5. $c = \mathrm{INV}\cos(\sin L_s \sin L_q + \cos L_s \cos L_q \cos v)$
6. $\beta = \mathrm{INV}\cos[(\sin L_s - \sin L_q \cos c)/(\cos L_q \sin c)]$
7. If $\sin v$ is positive, $B = 360 - \beta$. If $\sin v$ is not positive, $B = \beta$
8. $EL = \mathrm{INV}\tan[(\cos c - \frac{R}{R+h})/\sin c]$

where (all degrees are in decimal form, e.g., 24.1°):

L_s is the latitude of OSCAR in degrees — positive if north of equator, negative if south;

a is the inclination of OSCAR's orbit in degrees counterclockwise from east;

t is the time in decimal hours from T_x;

T_x is the time of a northbound equatorial crossing by OSCAR, in hours and minutes (GMT or local);

P is the period of the orbit in decimal hours;

λ_s is the longitude of OSCAR in degrees west from Greenwich, England;

λ_x is the longitude of the northbound equatorial crossing (at T_x) in degrees west;

λ_q is the longitude of the QTH in degrees west;

L_q is the latitude of the QTH in degrees — positive if north of the equator, negative if south;

B is the azimuth (bearing) to OSCAR from the QTH in degrees clockwise from north;

EL is the elevation angle to OSCAR from the QTH in degrees, from the horizontal upwards;

R/(R+h) is the ratio of the Earth's radius to the sum of Earth radius and orbit height.

Program steps 000 to 009 initialize the program, fix the decimal point to four places (necessary for accurate time displays later), print the entered time, T_x, convert T_x into decimal hours, store it in register 11, and halt, ready for the next entry. When λ_x is entered on the keyboard and RUN is pressed, steps 010 to 017 store λ_x in register 14, print it, and put a 0 in register 13. Steps 018 to 138 solve equation 1 and store sin L_s in register 63. Steps 039 to 080 solve expressions 2, 3, and 4. Steps 081 to 157 solve 6 and 8. Steps 158 and 159 test the elevation angle and, if negative, skip to step 214, after which Δt (your selected orbital time interval) is added to register 13, and the program repeats, beginning with

Table 1. OSCAR SR-52/PC 100A program.

step 018.

However, if the elevation angle tests as not negative, steps 161 to 211 add t to T_x, convert the result to hours and minutes, and print. Then they apply expression 7, print azimuth and elevation to the nearest degree, refix the decimal point to 4 places, and go to step 214, where the cycle begins again. Thus, a printout is made only when OSCAR is not below the horizon. Labels sin, cos, tan, and log are used internally to save program steps.

OK, so much for the sales pitch and the explanations — how do we go about using the program? Simple! Here is a step-by-step procedure:

FIRST — Key in the program listed in Table 1 (don't forget to either reset or GTO 000 before pressing the LRN key). Now, press LRN to put the calculator back into the calculate mode. Record the program on a magnetic card for future use. If you already have the program on a card, enter it in the usual manner.

SECOND — Key in the west longitude of your QTH (λ_q) in decimal degrees and STO 99; key in the latitude L_q in decimal degrees (if south of the equator, key +/- for the minus sign) and STO 98.

THIRD — Key in the following OSCAR orbit data, and store as shown:

1.916 STO 19 (P)
0.813 STO 18 [R/(R+h)]
101.7 STO 16 (a)
187.9 STO 15 (360/P)

(These values are averaged for OSCARS 6 and 7 and give good results for at least 36 hours of orbit. You can, of course, put more accurate values in if you wish.)

FOURTH — Key in your desired orbital time intervals (Δt) in decimal hours; e.g., if you want 4 minute Δt, key 4 ÷ 60 =, and store the result in register 17 by STO 17. (This will store 0.0666666667 in reg. 17 for this example.)

FIFTH — Set the R-D switch to D (degrees).

This completes setting up the calculator with its permanent data base. Note that, if you have already used the program, then replaced the program with another to work on some other problem but have not turned off the calculator or otherwise disturbed registers 15 through 19, 98 and 99, the second through fourth steps can be omitted.

Now let's take an actual example (which can be used by you as a "check" problem), using my QTH (L_q 32.75, λ_q 117 are stored in registers 98 and 99), and OSCAR 7, beginning on the evening of July 3, 1977, Pacific Daylight Savings Time. Page 16 of the July, 1977, issue of *73 Magazine* lists orbit 12044, A mode, July 4, 0138:05 GMT, 78.1°. This is July 3 at 1838:05, my time. When I enter T_x, I can use either GMT (1.38) or PDST (18.38), as I choose. The resulting times will then be in the same time zone. I will choose PDST and enter to the nearest minute in H.M (Hours.Minutes) as follows:

STEP 1 — (optional) Key 703.77.07 PRT to print my Pacific date and indicate OSCAR 7 (07).

STEP 2 — Key 18.38 (T_x in H.M).

STEP 3 — Press A (the calculator will stop, showing 18.6333, which is T_x in decimal hours, and will print 18.3800 PRT).

STEP 4 — Key 78.1 (λ_x).

STEP 5 — Press RUN.

Now you can relax and do other things, as you wish. The calculator-printer has taken over. It will immediately print 78.1000 PRT, thus giving you T_x and λ_x for reference. It will then print out the time (in H.M), azimuth, and elevation angles in degrees every 4 minutes of orbit time that OSCAR 7 is within the QTH's horizon, throughout the rest of the

night of July 3 and throughout July 4. It takes the calculator about 13 seconds for each Δt, thus the first printout will be about 40 seconds after you pressed RUN, because the satellite is not above the horizon until 18.46. At that time, the azimuth is 99°, and the elevation is 8°. It will take the calculator approximately 70 minutes to finish 24 hours of orbit time, and thus about 1½ hours to finish the July 4 evening passes. Fig. 2 is an actual PC 100A tape for this example.

OK, you say, that's fine for a west coast ham, because the orbits listed in *73* are usually the first ones that are within range of the west coast. But how about someone on the east coast? It's still simple: Take that orbit for July 4 GMT, and subtract 115 minutes and 28.75° several times from the listed values in *73* until you get the T_X and λ_X of the first orbit that will be in your range. I have found that the first northbound orbit must be about 65° or less east of my QTH to be within range; this should be suitable within the 48 states and Hawaii.

Or, for the really lazy (or busy?), just start with the preceding day's first orbit, as listed in *73*, and let the calculator crank out about 36 hours of orbital data. This suggestion is probably the easiest for hams in the equatorial and sub-equatorial regions to use, because their usable passes will be either northbound passes, starting from below the equator, or southbound passes.

Well, so far so good, for the fat cats with the printers; now, how about those of you with the bare bones SR-52? Here's how: First, put in the program and data registers, just as indicated earlier, but with 3 simple changes. Change program steps 185, 205 and 209 from prt (98) to HLT (81). The calculator is used in the same way, except that paper and pencil are used instead of the automatic printer.

After T_X and λ_X are entered as above, the calculator will halt and display the first time the satellite is in your range. After writing it down, press RUN, and the calculator will halt with the azimuth displayed. Write it, press RUN, and the calculator will halt with elevation displayed. Write it, press RUN, and a new time will be displayed when the calculator halts, etc., etc. However, remember that each calculation cycle takes about 13 seconds, so that, if the satellite takes 12 minutes to come into range, as in the example above, it will be about 40 seconds before the calculator halts with the first time display, and, after the OSCAR goes beyond your horizon, it will be about 5 minutes before the calculator halts with the next northbound pass in range displayed. It will be much longer than that, after the last northbound pass, until the first southbound pass comes within range. You may find it more convenient to press HLT, if no display has appeared in 20 seconds after a series of displays. Then, add (use the calculator for this; it won't hurt the program) 115 minutes to the previous T_X and 28.75° to the previous λ_X, enter these new values for the T_X and λ_X in the program, and you thus bypass the time to circle the world. A convenient way to do this is to key in the previous T_X (e.g., 18.38), press D.MS, +, RCL 19, =, INV D.MS, and then press A. At the halt, key in the previous λ_X (e.g., 78.1), press +, 28.75, =, and then press RUN.

Well, there it is. Have fun with the program and good hunting on OSCAR. ■

Try A T-R For OSCAR 8

-- turnstile over reflector system

David J. Brown W9CGI
RR 5, Box 39
Noblesville IN 46060

T-R, in this case, is *T*urnstile over *R*eflector antenna, and it could definitely aid your OSCAR performance. Built for three band capability, it will do well for you on the present OSCAR satellites, not to mention the upcoming AMSAT high orbit type machine. If you think using mechanical tracking rotors for the present OSCARs is tough, the next one is going to be impossible for you. True, it moves more slowly, relative to a position on Earth, but I'm sure we will hear the same, "Where the heck is it?" comments we had about OSCARs 6 and 7.

Referring to Fig. 1, I have only shown the two-band 2m/10m version, because that is all I have had a chance to check out. There is no reason at all why two ten-foot masts could not be used in place of the ten- and five-foot versions shown for the vertical mast. An alternative is to build it as shown, and, due to the very small size of the ¾m version, it could even be bracketed to the top at a later date. That is my reason for drawing the unused extra ¼ wavelength of mast poking out of the top on 2m.

Construction is entirely with commercially available antenna parts (especially from Hy-Gain 64Bs). The crossed dipoles on the 10m T-R can be 10m beam driven elements. Two of these are used on mine, less the beta matches, and with the elements stretched out to 10m dimensions. I did this by using some CB antenna aluminum tubing. These tubes were the same o.d. as the tube/reducers on the original 64B and fit nicely into the 64B dipole insulators. The old 64B element o.d. is not quite the same as the i.d. of the new CB tubing, but there are ways around this. You can wrap the smaller element with aluminum foil and then clamp it into the larger element with hose clamps, or go the more complex route I went. I added plugs about 2 inches long, that were bored out and tapped on one end to 3/8-24. This exactly matches the threaded stud on a full-size stainless steel CB whip. I obtained several of these whips, that had been damaged in one way or another, but still had good studs and about 40 inches plus of undamaged whip. If you figure out the average height of a car versus a bumper-mounted CB whip, believe me, there are several whips in this condition around. They are worthless to use on CB, so you can buy them even cheaper than the replacement full-size whips. My CB aluminum tubing came out at 56 inches, so the whips were cut off at 39 inches and screwed into the plugs. The plugs are held in the tubing by ¼-20 hardware through the tubing and plug.

For the reflectors, I used the CB parts that would normally be the ground plane elements. The largest parts just fit the same insulators, and then are grounded to the

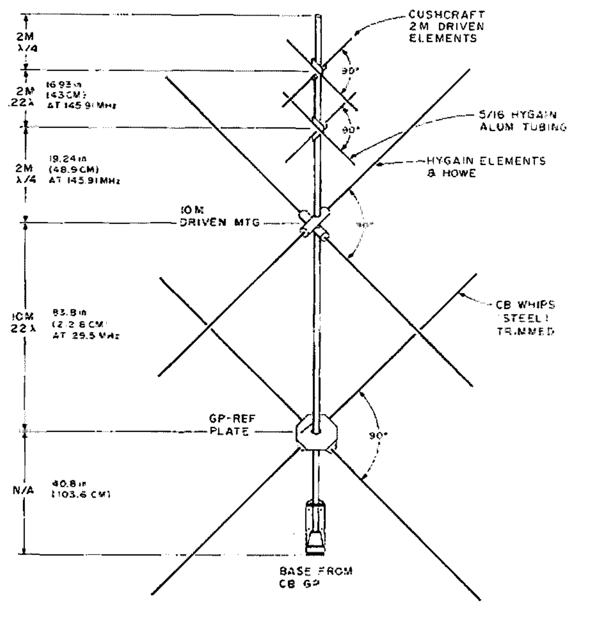

Fig. 1. Vertical mast is 10' x 5' heavy-wall TV mast (bolt through joint). Cut off lower flare to fit into or onto CB base used.

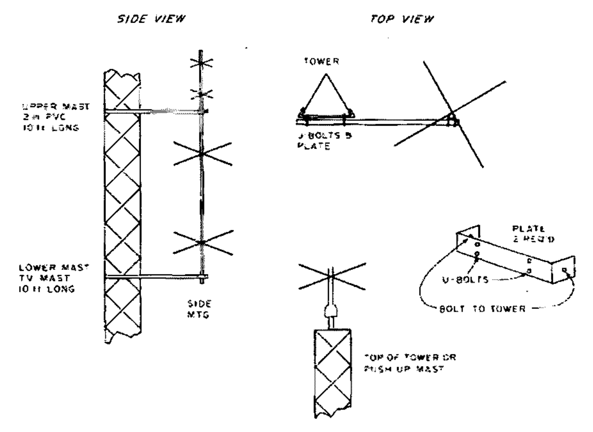

Fig. 2. Mounting.

	General	@ f_o in Fig. 1.
2m driven	$234/f_o$	19.24" 48.9 cm
2m reflected	$234/f_o$ + 5%	20.2" 51.32 cm
10m driven	$234/f_o$	95.2" 241.8 cm
10m reflected	$234/f_o$ + 5%	99.94" 253.86 cm

Table 1. Mast CTR to tip of element.

boom by a 1-inch wide strap, from feed clamp to boom to feed clamp. If you order parts, just use the director clamps instead, and the element will be already grounded.

The 2m T-R is not much different. You can even use a plate and CB whips (or the parts cut off above) to make the reflector elements. You only need pieces about 20 inches long. Simple brackets will mount them to the vertical mast.

The driven elements are made to order, used as is, parts from the A147 type CushCraft antennas. They are just the driven elements from those antennas. When I lost the EME array a while back, I saved the parts off the broken 3 yagis. They are 50 Ohm, coaxial-fed dipoles with gamma matches, so it can't be much simpler. Even their mounting method is obvious from their construction.

All that leaves are the matching harnesses. A letter to Hy-Gain produced the figure of 200 Ohms for a feedpoint impedance using the dipole alone – no beta match. The harness of Fig. 3 shows the material and cutting instructions. Use good lugs on the bolted connections, tape well, and use a good quality, clear spray liberally. Since the clear sets up so rapidly, I have found 4 or 5 light coats work better and crack less.

The 2m harness is even easier, since it uses all coaxial connectors. Measure and solder carefully, and check all the harnesses piece by piece for braid to center shorts, as each piece is completed. Then screw it all together and to the antennas, and tape and spray well. Nothing is more disgusting than to build a good antenna and have it die a month or two later, so please forgive me for belaboring the tape and spray routines.

Fig. 2 covers mounting possibilities. The array size, weight, and low wind load make it a reasonable candidate for chimney mounts. Just remember this is a last resort spot for antennas. It is the most corrosive, thermally changing, lousy spot available, but if it's all you have, it's all you have. I used the side bracket method, with the lower ground planes about 20 feet off the real ground. It is on a tower that also has two stacked halos for a backup on 6m and the Hy-Gain 66B 6m yagi up on top. None of the 6m goodies seems to cause shadows or create any loading effect problems. It all looked the same looking into the feedpoints up and mounted as it did on the ground. The 2m swr was very good at 1.15:1, and it is not worth messing with to improve. The 10m must be getting a little pattern distortion, no doubt from the tower; but it had a 1.1:1 on the ground and a 1.25:1 now. It works fine, and I'm not going to push it to get a little more here and there.

This whole story seems terribly short, but then there just was not much to the construction, either. One weekend of an hour here and an hour there, and it was both done and up. The antenna design is not new, but I thought you might like to share some of my construction methods.

Here's one final note of help: When you get it all together, try the following: As the beast gets larger (as you add the 10m hardware), it pays to have a pipe stuck in

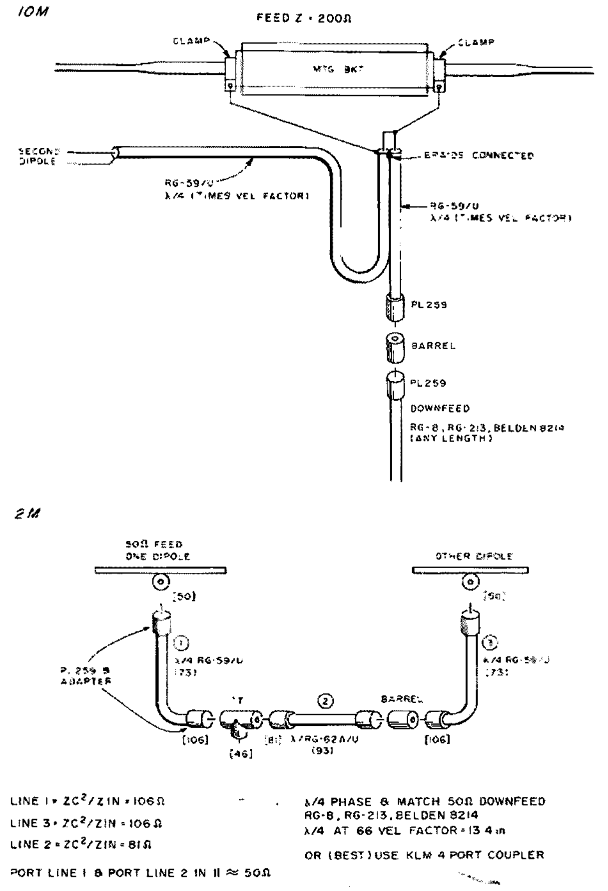

Fig. 3. Feed and phase.

the ground that you can U-bolt it to and work on it upright. I have a 4-foot pipe stuck 3 feet in the ground in a post hole and filled around with concrete. Level the concrete off with the ground in sympathy for your lawn mower. Don't place it where you can break a leg on it, and you have a utility mast and antenna holder. If you saw the expanded end off of a TV mast (as you will do in making the vertical mast in this article), and make the cut-off piece about 8 inches long, you will end up with a dandy test setup. Keep two 10-foot TV masts around (up in garage rafters, etc.), and, if you fit them together to make a 20-foot mast, add the sawed off piece to the unexpanded end of the 20-foot pair, use the whole business upside down (expanded ends up), and choose your 4 feet of water pipe in the ground with an ID larger than the TV mast (but smaller than the expanded part), you wind up with a quicky test setup for checking out small antennas at 21 feet off the ground. Even some of the small and lightweight 6m beams aren't too big to swing up. For larger antennas, two water pipes in the post hole, with the mast pivoted between them (tilt-over tower style), also work well.

Keep me posted on how it all works out for you, preferably when I hear you having fun on OSCAR. I mounted mine in a direction southeast from the tower, due to the tower sides' orientation. The way the legs are on my tower left me the general directions of 0, 120, and 240 degrees, so I chose the 120 degree direction. I favor the early evening passes east of me, since I can be home and make more of them. It also does just fine on passes west of me, too, so have no fear of it being deaf off the tower side. See you on OSCAR. ■

Track OSCAR In Real Time

-- with your HP-67 calculator

Program Description

H-P 67/97 CALCULATOR

Program Title: OSCAR TRACK
Name: T.A. Prewitt, W9IJ Date: 5/22/77
Address: 2212 S. Webster
City: Kokomo State: IN Zip Code: 46901

Program Description, Equations, Variables, etc. Adapted from equations given in Computerized Satellite Tracking, 73 Magazine, February, 1977, page 72, by WBØJHS.

Store these constants in the indicated registers:

4 Longitude increment (28.7363)*
5 360
6 1/60
8 Inclination to equator (101.77)
9 Period (114.945)
12 -1
13 360
15 Height (910)
16 Latitude of your station
17 Longitude of your station
18 3959
19 69.09

*Values in parentheses are for OSCAR VII

Operating Limits and Warnings: Program has been checked for station locations in North latitude and West longitude. Should work for East longitude if longitude is complemented.

DO NOT USE THIS SPACE

				Time
4.	To Track AZ-EL in Real Time During A Pass, First Perform 1, 2 and 3 (If Needed). Wait Until Real Time Reaches Time Shown In Display		A.	Note 1
	Note 1 - Display During Track Mode Consists Of Elapsed Time In Minutes, Followed By A Zero and AZ-EL Bearings. AZ Angle Appears Immediately To Left Of Decimal Point And EL Angle Is Immediately To Right Of Decimal Point, Which Serves Only As A Separator. EL Is Zero If Satellite Is Below Horizon.			

In the February (1977) *73*, Henson* presented a beautifully-documented mini-computer program for tracking OSCAR. The program described here calculates and displays the same information (except range), and, in addition, runs in real time during a satellite pass. Written in RPN for a Hewlett-Packard HP-67 pocket calculator, it will run on an HP-97 as well. I'm sure that an equivalent program could be written for the TI SR-52, although I have not done so.

After loading the program and data constants, begin by entering reference orbit data. Then step ahead one or more orbits to the one of interest. The calculator will pause to display the orbit number and the longitude of the equatorial crossing, and will halt with the display containing the predicted time of the equatorial crossing (with all data needed for a real-time track of the satellite on the selected orbit stored in the proper registers).

When real time (clock time) reaches the time shown in the calculator display, press the "TRACK" button to commence a real-time track. Thereafter, the program will run continuously, calculating beam-aiming data once each minute, and pausing every few seconds to display the current results.

Several data display formats have been programmed and evaluated. Although many tracking parameters can be calculated, the ones finally selected for display are the elapsed time, the beam heading, and the elevation angles. To keep the waiting time between successive displays to no more than a few seconds, these three data items are merged into a single line, which is displayed three times as frequently as each would be if they were displayed in sequence.

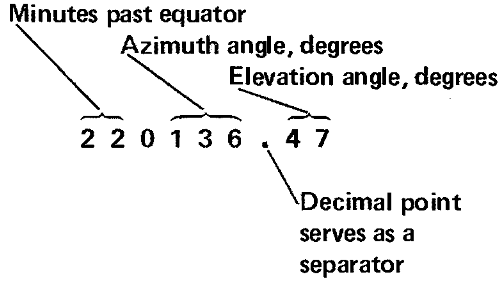

Fig. 1. Typical merged display.

Fig. 1 shows a typical merged display. The elapsed time, in minutes, appears to the left of the first zero. The azimuth heading appears to the left of the decimal point, and the elevation angle is shown to the right of the decimal point. Both angles are in whole degrees, and the decimal point serves only as a separator. The elevation angle will be shown as zero if the satellite is below the horizon.

Approximately thirty seconds of each minute are used in calculating and formatting new data, and the remaining thirty seconds are devoted to six 5-second data displays, which are distributed throughout the one minute period. If your calculator runs the program correctly but completes a loop in less than sixty seconds, add one or more PAUSE commands at the end of a display to pad it out to a full minute.

After the program is running correctly, record it on a program card and save the contents of the registers on a second data card. ■

Logical Thoughts About OSCAR

-- meaningful to computers!

Wm. Denison Y. Rich OA6AD
Casilla 751
Arequipa, Peru

Several months ago I received a free copy of *Ham Radio Horizons* and read the article about the OSCAR (Orbital Satellite Carrying Amateur Radio) satellites.[1] Up to that time, I had heard of OSCAR but supposed I would need a good deal of auxiliary equipment to access the satellites. However, according to the author, my trusty SB-102 should have been able to hear either of the OSCARs. The only problem was when to listen. Since the maximum exposure (during an overhead pass) is a little more then 20 minutes, and there are, at most, four favorable passes per day, random listening is definitely out.

At the time, I recalled that the ARRL was publishing AMSAT-supplied[2] equator crossings for the OSCARs in daily CW bulletins. A day of poking around in the QRM/N on 20 (why does everyone tune up on 14.080?) netted me a dozen crossings, and, with a dandy desk calculator, I was able to fill in the gaps and make several days of predictions.

Shortly after, I heard OSCAR 7 on one of the passes I had predicted, and I was hooked. I also heard half a dozen or so stations working through the satellite and am now working on a solid state, 2 meter CW rig (you convince *your* wife you absolutely must have a new $700 transceiver, so you can talk to a satellite) and some sort of antenna to go with it.

But, if I can do these predictions on a desk calculator, why can't I do them on a computer?

At work (oddly enough, a satellite tracking facility of the Smithsonian Astrophysical Observatory), we have a NOVA 1200 minicomputer.[3] Since this machine is available for some time each day, the next step was to write a program to predict successive OSCAR passes.

Language

Although we have two more efficient languages available, I chose to use BASIC[4] (DGC Extended BASIC as modified by COI[5]) for three reasons:

1. BASIC is one of the most easily understood languages available. Its clarity far outweighs any lack of speed, especially for the beginner. In this case, speed is no consideration anyway, because the actual computation takes only a few milliseconds, with most of the program time spent in controlling the teletypewriter output device.

2. BASIC is widespread. Most school computers, be they in high schools, colleges, junior colleges or even in grade schools, run in BASIC, in addition to other languages. The chances are good that, if you have ever used a computer, you have programmed in BASIC.

Check with your local school board or with the science and math departments in your school system. If the school does have computer facilities, this might make a nice tie-in for a new educational use for OSCAR.

3. Many advertisements for microprocessor/computer systems list BASIC as a ready-to-run language, either supplied or available as an option.

Programming

For any nontrivial program, a flowchart is almost essential and is an easy way to block out the job. The flowchart will usually suggest ways of breaking up one large job into several smaller ones. Fig. 9 shows some commonly used flowchart symbols and their meanings.

In the main chart for this program (Fig. 1 and Fig. 10, lines 1 through 299), each phase of the program is represented by a separate block. Some blocks stand for a single instruction, but most stand for two, three, or more.

Fig. 1 begins with the block RUN and "flows" in an orderly manner to the block END. Some of the blocks (SELECT A SATELLITE) stand for what are called subroutines. A subroutine is a short program which takes care of some special job, like selecting the elements for a particular satellite. Usually, a subroutine is written because the same small job is to be performed several times, and there is no sense in repeating the same "code" over and over.

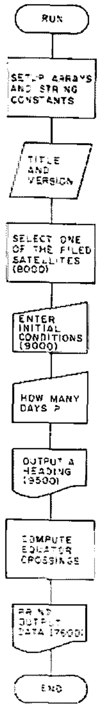

Fig. 1. Main program flow showing data entry points, computations, output points, and major subroutine calls.

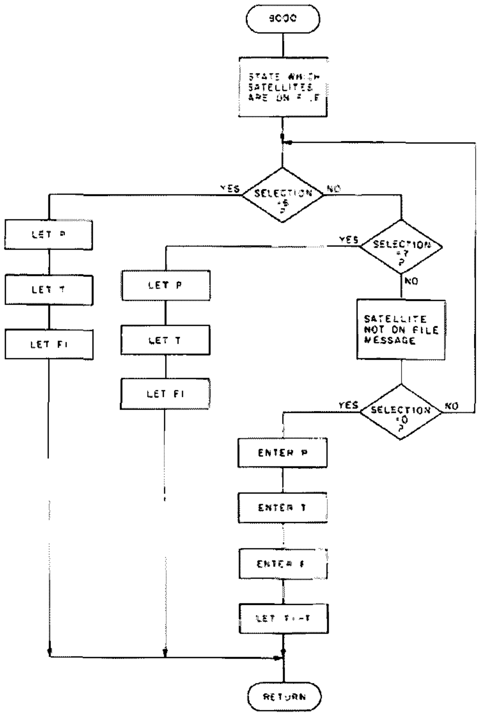

Fig. 2. Subroutine 8000, which is used to select either a filed satellite or a new, unfiled satellite.

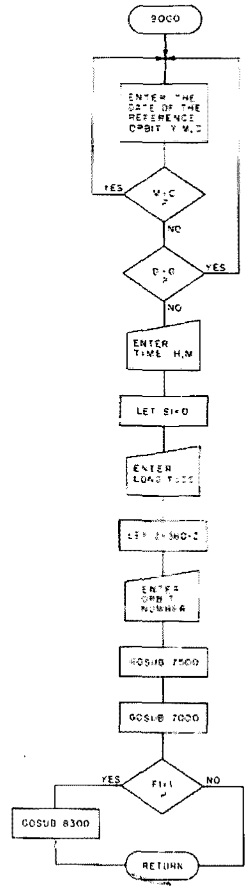

Fig. 3. Subroutine 9000, which is used to enter the reference day and position for the selected satellite.

Quite often a stock subroutine can be used in other programs with little or no modification. For example, I have already used the "calendar" subroutine (7000) in two other programs.

I like to use subroutines to make the big job smaller and easier. If all the subroutines used in this program were combined into a single program and flowchart, we might need a square meter of paper on which to draw it and, certainly, a tour guide to help us through it.

An "ultimate" main program might even begin at RUN, consist of nothing more than GOSUB statements, and finally terminate with an END statement.

To keep things simple:
1. Break up the big job into individual steps.
2. Keep the "main" program and its flowchart in as straight a line as possible.
3. Document your program with explanatory remarks wherever possible. If you decide to make changes in 6 months, you'll be awfully glad you have these notes.

In BASIC, it is not necessary that line numbers follow sequentially. The program always goes to the next highest line number for execution (unless, of course, it encounters a GOTO, GOSUB, or RETURN statement).

I like to think of the available program area (lines 1 to 9999) as a notebook. Early "pages" are used for the main program, with plenty of blank pages left for later changes or corrections; later pages are used for subroutines, filling the "book" from the back toward the front. If you put everything in the front of the "book," and then have to rewrite some section or insert corrections, you will have a major rewrite job on your hands because of the lack of vacant line numbers ("pages").

Equator Crossings

The objective of this program is to produce OSCAR equator crossings (time – UT, longitude – W), based on reference orbits (initial conditions) supplied by AMSAT via W1AW.

In the following discussions, no attempt is made to explain, in detail, the workings of BASIC. It is assumed that, if you have access to a computer and BASIC, you also have access to any necessary "how-to-use" manuals.

Lines 1 and 2 (Fig. 10) are self-explanatory. Lines 10 through 39 are used to set up several constants and an array, all of which will be used later by different sections of the program. Lines 40 and 41 are the "TITLE" block of Fig. 1, followed by line 55, which sends us to the "SELECT-SATELLITE" subroutine, beginning at line 8000.

This subroutine (lines 8000 through 8201 and Fig. 2) tells us which satellites are preprogrammed and asks which we want. Lines 8025 and 8030 direct the flow to the appropriate set of elements, each of which is terminated by a GOTO 8200. Line 8200 announces the chosen satellite, and 8201 contains the RETURN statement, which must end all BASIC subroutines, and which transfers control back to the main program. Lines 8063 and 8083 set the state of a flag, F1, which will be used later to help format the printed output of the program.

If the tests in lines 8025 and 8030 fail, then line 8040, the next instruction in sequence, sends control to line 8090. These are self-explanatory, except for line 8140, which converts the westerly drift, entered by the operator, to easterly drift, the form which will be used by the program in its calculations. We will, of course, convert the output back to westerly degrees before printing.

New satellites may be programmed by inserting an appropriate test in the decision chain, starting at line 8025, and, of course, a block of elements ending with GOTO

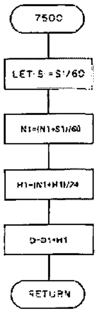

Fig. 4. Subroutine 7500, in reality only one line long, but shown here as 4 separate steps in the interest of clarity. This subroutine converts integer hours, minutes, and seconds into decimal parts of a day, and then adds this number to the current day.

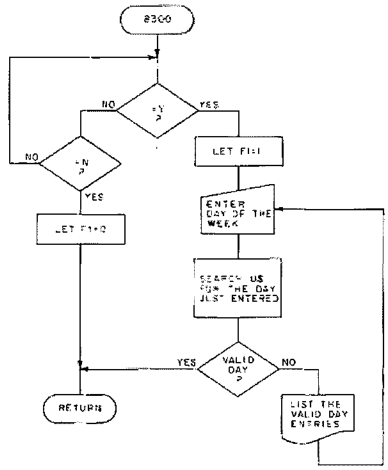

Fig. 5. Subroutine 8300, which sets up the flag, F1, for later use by the output routine. In the event that the unavailable days are to be suppressed, the day of the week for the reference orbit is entered here.

8200. One would also change line 8000. The element block may go anywhere in the subroutine, provided that the elements end with GOTO 8200.

Now, go back in the main program for a second. Line 70 transfers control to the subroutine at line 9000 (Fig. 3).

Lines 9000 to 9040 are self-explanatory. Line 9045 is included because time is only requested to the nearest minute, but, since seconds (S1) are used in the calculations, S1 must have some value. If, later, you want to include seconds as an input variable, the only change needed will be to delete line 9045 and add S1 to the input lines, 9035 and 9040. S1 is already included in all pertinent calculations.

Once again, line 9053 converts west longitude to east longitude, just as was done back at line 8140.

At line 9065, we find another subroutine call. Subroutine 7500 (Fig. 4) is a one-liner which turns seconds, minutes, and hours to decimal parts of a day. "Decimal" days are by far the simplest way of keeping time in a program!

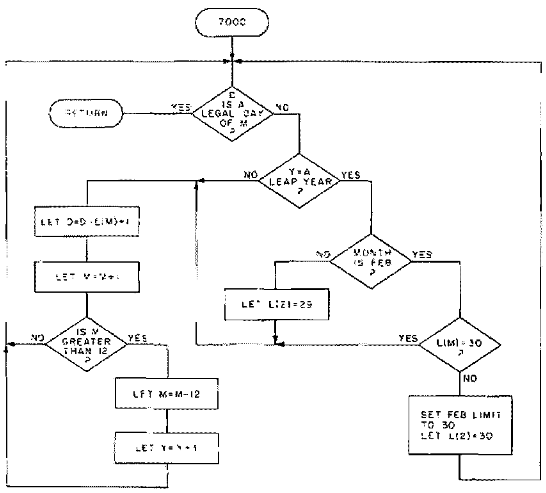

Fig. 6. Subroutine 7000, the calendar subroutine which takes care of advancing the month and year, when required. This subroutine also takes into account the possibility that the current year is a leap year and that, therefore, February must have 29 days instead of the usual 28.

After returning via line 7550, we are immediately sent, by line 9070, to subroutine 7000 (Fig. 6). This is the calendar manager and is perhaps the most complex subroutine in the program. What does it do?

First, it checks to see if the current day is still inside the current month. If it is, then control is passed right back to the calling program. If not (say we had typed FEB 29), the subroutine checks to see if the current year is a leap year. If this is so, the limit day of February is set to 30, if not already so set, and the current day is again tested at line 7020 to see if it has become a legal day by virtue of the limit change. It is the accounting for leap year that makes this subroutine so complex. Without leap years, the only branch would be the first one, at line 7020.

If the current day still fails the test at line 7020, then we must move on to the next month, so lines 7038 through 7060 are executed, and a return is again made via line 7020. This last test is cheap insurance against having created an illegal day.

If line 7045 finds month (M) value greater than 12, it increments year (Y) and returns via the legal day test.

Note that, if the test "L(2)=30?" is not included at line 7085, one logical course of action, after finding that the month is February, would be to set the limit to 30, then reenter at line 7020. This is okay until the day gets to be February 31 or greater, at which point the program has no way of breaking the loop and performs: (LEGAL DAY?) – (MONTH IS FEB?) – (SET LIMIT = 30) – (LEGAL DAY?) – (MONTH IS FEB?) – etc., – etc. . . ., until the cows come home. Flowcharts are a great help in avoiding this sort of bug.

Now let's go back to line 9073 – that is, just following the subroutine call to the calendar manager. Remember, we are entering initial conditions for a prediction run. Only one more parameter needs to be checked – the flag, F1. This is done at line 9073. Subroutine 8300 (Fig. 5) is called, if necessary, and asks if you want all crossings or only those available for use. So far, only OSCAR 6 has a serious restriction, but, since any satellite might have one, the option is included. Return is made to the calling subroutine and then to the main program via line 9075.

Lines 80 through 130 of the main program are self-explanatory. Line 140 sends us to subroutine 9500 (Fig. 7), which will print the satellite number and date for each

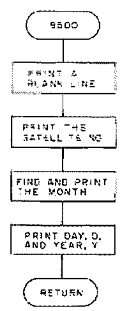

Fig. 7. Subroutine 9500, which prints headings for each day's passes. These headings will be printed even if the output for a particular day is suppressed.

new day predicted.

The actual calculation loop, lines 150 through 195, is executed (13 x I)/S times. See lines 80 through 100 for I and S. Subroutine 7600 (Fig. 8) is the output routine and immediately calls the calendar (7000). Subroutine 7600 then checks to see if this is a new day (line 7612), and, if it is, calls for a heading to be printed.

The decimal day is converted to a day, hour, and minute (lines 7682 through 7691). The orbit number and time are printed (lines 7693 and 7696), and the longitude is converted to west and printed by line 7698.

The odd decision chain, at lines 7625 through 7635, tests the value of F1, which was set up back at lines 8063 and 8083. If F1 is nonzero, only the "available days" are printed. More available days could be added to the chain, if needed.

Note that, since the "new day" test (line 7612) is done before the test of F1 (line 7620), a heading will be printed for every new day, even though the passes for that day are suppressed. The heading doesn't take much paper and lets you see at a glance what the program is up to.

Fig. 11 is a sample run. All human typing is underlined. Computer output is not.

Simplicity or Flexibility

A program such as this requires a lot of work to write, especially when compared with the actual amount of calculation it does. But it takes me several hours to prepare 30 days of predictions, not counting my penchant for arithmetic errors, while the machine can compute and print the same number of predictions in about 20 minutes, with no errors, provided it is programmed properly. Thirty days comes to about 400 crossings.

The amount of work required to prepare this and, perhaps, most programs can be justified only if an equivalent or greater amount of time can be saved later on. It is for this reason that the program was made flexible. A simpler program would not have options like the choice of satellites preprogrammed, entry of trial satellites, and the like. For a little extra work now, I have a program which allows me to file a new satellite in a matter of minutes or to run a trial on a new satellite at the cost of entering its period and westward drift. I can easily suppress output of any day's passes, and the days to be suppressed can be changed by changing only one or two lines.

When OSCARs 8, 9, and 10 come along, this program will be running within minutes of my receipt of the necessary data.

Speaking of data, you may get it from a magazine article, as I did, or you could compute it, if you know any two reference orbits, ORB1 and ORB2. It helps somewhat if the two known orbits are a few days apart.

Period = P = (TIME2 - TIME1)/(ORB2 - ORB1)
Drift (W) = T = (LAT2 - LAT1)/(ORB2 - ORB1),

where TIME and LAT are the initial conditions for two crossings, and ORB1 and ORB2 are the orbit numbers.

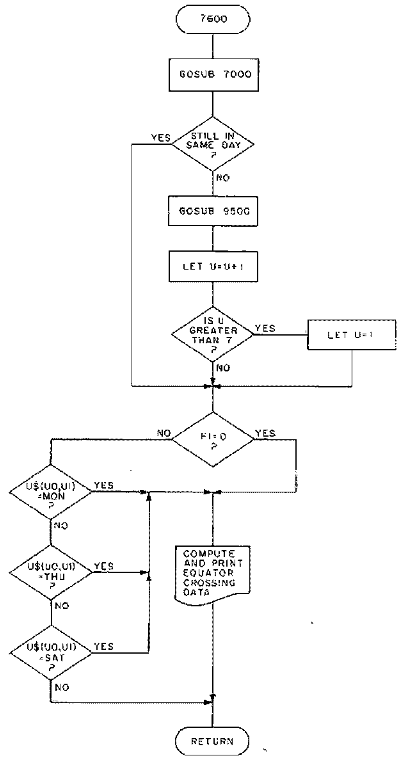

Fig. 8. Subroutine 7600, which causes a heading to be output, if necessary, and then decides which, if any, of the crossings will be printed.

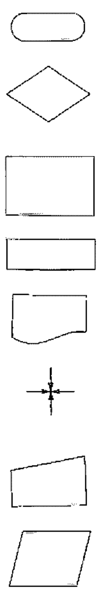
One further improvement might be to add a longitude test to the output routine, such that only passes which will be "visible" from your station will be printed. This would drastically cut the total running time.

Parting Thoughts

Keep track of the residuals, or the differences in time and longitude, between



Usually used to signify a start point (RUN) or an END. Also used for entry and exit points of subroutines.

This symbol always signifies a decision point. Usually the branch paths run out from the side of the diamond; however, this is not necessary if the paths are clearly marked — yes, no, true, or false.

This and the following symbol describe any "process." A process may be a GOSUB, GOTO, LET, PRINT, or any other operational instruction.

Output, in the form of a printed document. This symbol may be used for either teletype or line printer output.

These arrows indicate program flow. They are one-way only, like diodes. Once flow has passed through an arrow, it may not go back. In this example, there is an insolvable problem in that all four arrows point into the intersection. There is no exit!

Input, usually from a keyboard terminal.

Comment, either an output from the program or an explanatory block for the programmer. This symbol does not have to represent a section of the program.

Fig. 9. Some of the symbols used in flowcharts and some of their possible meanings.

your predictions and the W1AW bulletins. I once predicted OSCAR 7 for 30 days, only to discover later that there was a 10-minute bias to all the times because the reference orbit had been wrongly copied from W1AW. Typical residuals, over a 30-day prediction cycle, have been ±1 minute and ±.1 degree of longitude. These differences creep in mainly because the AMSAT/W1AW bulletins only give time and longitude to these accuracies. We cannot expect the program to be more accurate than the data given it.

This program is only one way of reaching the stated objective. There are usually as many programs per problem as there are programmers

Fig. 11. A sample run for OSCAR 7. Human input to the program is underlined. Everything else is the product of the program.

attacking the problem. In this case, for example, certain sections of the coding were made to take up several lines, where only one line was really needed. This has resulted (I hope!) in greater clarity at the expense of space. Why not try improving this program?

Not all BASIC versions are identical. Make sure the features I have used are available in your version of the language, before writing a stiff letter to the editor.

Important note: When listing a program, this particular version of BASIC often inserts phantom spaces. These are only important in the following lines:

Line 17 must begin "SUNMON..." with no spaces between the quotation marks and SUN. "...FRISAT " does include 3 spaces following SAT, and then the quotation mark. Line 18 is similar to 17 and must begin "JANFEB ...", without spaces after the leading quotation mark. There are no spaces following DEC.

Lines 7625, 7630, and 7635 are similar in that the test day, for example "MON", must be enclosed in quotation marks without spaces as "MON", "THU", or "SAT".

Lines 8330 and 8340 are the same; the Y and N must be entered as "Y" and "N", without enclosed spaces.

All other blank spaces in Fig. 10 are not critical and may be inserted or deleted according to your whims or the requirements of your flavor of BASIC. ■

RTTY Loop

I hope you enjoyed the special RTTY issue! Now that you are completely ready to operate, a few hints and suggestions are in order. Required equipment is a printer/keyboard combination (Model 15), a loop supply, a terminal unit, and an AFSK generator. I assume that you already have a transceiver capable of operating SSB on the low bands. Let's get started!

RECEIVING RTTY

By convention, RTTY operators congregate on certain areas within the CW portion of the band in question. There is activity on both 80 and 20, not much on 40, 15, or 10. Eighty meter activity is usually found around 3615 kHz and up. Twenty meter teletype freaks are found from 14.08 to 14.1 MHz. Sideband conventions are reversed on all HF bands except 80. Therefore, RTTY is received and transmitted on lower sideband on twenty — voice is upper. On 80, SSB and RTTY are both transmitted on the lower sideband.

In order to properly receive RTTY, the signal must be carefully tuned. Allow your transceiver to perk for an hour or so before tuning up the first time. An audio sample must be coupled to the TU ... normally through a matching transformer. Many of the popular TUs such as the HAL ST-6 and Flesher DM-170 require a 500-600 Ohm feed for proper operation. In a pinch, however, the TU can be paralleled across the speaker line. There are two common methods for tuning a RTTY signal. The first, and easiest, method employs a meter. The TU meter indicates a steady value when the signal is properly tuned — if not, it will jump randomly in the presence of RTTY or CW. Carefully tune the receiver until the meter is steady ... it's best to start out on a strong signal! Consult the operating instructions for your particular TU for specific details. The second tuning method uses an oscilloscope with the horizontal sweep disabled. Almost all TUs have "scope output" terminals which allow the mark and space discriminator output to be coupled to the scope. When receiving a RTTY signal, a pattern of crossed ellipses or circles will be present. The technique is to tune the receiver until the elliptical patterns are as large as possible, and as close to right angles to each other as possible. Most modern TUs have both scope outputs and meter tuning; try the meter method until you have the hang of tuning RTTY.

At this point, you should be able to copy amateur QSOs. Saturday afternoon is the best for 20 meters — if you are lucky you'll hear Ricky WAØCKY transmitting one of his classic RTTY pix! You should also hear (see!) stations calling CQ. If you're ready to answer, read on!

TRANSMITTING RTTY

Transmitting is simple. The output of your AFSK generator is connected to the microphone input of the SSB transceiver. When the loop is keyed, either by the keyboard or tape reader, the AFSK oscillator converts the Baudot pulses into frequency shifted mark and space tones. A caution is in order at this point: RTTY, like CW, is a continuous duty transmission. Unlike SSB, RTTY imposes extra strain on the final of your transmitter. It is wise to derate SSB ratings by a factor of four — if your rig is rated at 200 Watts PEP, do not allow the continuous RTTY output to exceed about 50 Watts. Save a tube! You will soon find that most RTTY operators do not use high power ... like CW, a bit goes a long way. In most cases, 200 Watts and a beam will do the trick. I run 75 Watts, and have needed more on few occasions.

When using a standard SSB transceiver, use 170 Hz shift. This insures that the audio tones are well within the passband of your transceiver's filter. It is possible when using 850 shift to produce a secondary, and illegal, carrier. Most current activity is on 170 shift anyway.

An aside: A good beginner's RTTY transmitter is an old Heath HW-32 20 meter singlebander, popular a few years ago. This rig is designed for phone only service, but can be put on RTTY (or CW) by changing a single crystal. I performed this modification, and threw in a new filter crystal to be safe. The HW-32 will put out 40 Watts continuously, using sweep tubes in the final.

Although this issue marks my last as Executive Editor of *73*, I'll still look forward to seeing you on 14.090 or 3615 in the evening!

John Molnar WA3ETD
Executive Editor

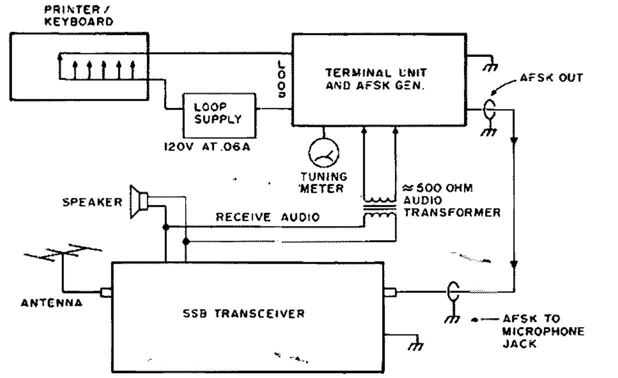

Fig. 1.

Many modern terminal units use a meter for tuning. A steady value indicates a properly tuned RTTY signal. Once the signal is tuned, the printer can be activated. The TU pictured is the HAL ST-5000.

OSCAR DX

-- a new challenge

At one time or another, each of us has experienced difficulty in working DX stations because the HF propagation has been poor. We now have an alternative. With amateur satellites it is now possible to communicate consistently with stations up to 4500 miles away and predict exactly when they can be worked without the propagation problems incurred at HF.

A number of well-known HF DXers are now quite active chasing DX via amateur satellites. In the United States, in less than two and a half years, Ben Stevenson W2BXA has worked 86 countries via satellite. Actually, Ben and Pat McGowen G3IOR are having a battle to see who will be the first to work DXCC via satellite. Pat has at least 86 countries worked to date. Bill Hunter K4TI did a study several years ago and concluded that DXCC was possible via the present OSCAR satellites. Today with OSCAR 6 and 7 it is possible to communicate with amateurs in Europe and Africa every morning and early evening. On subsequent passes, amateurs in South and Central America as well as the Caribbean and Asia (AU9 and Ø) are within range. Between 0300 and 0500 GMT the satellites are passing over California, which brings the KH6s in range. And we can work these DX stations every day, day after day. In fact, when HF propagation disturbances occur occasionally, satellite communications are even enhanced.

As a matter of history, in mid-October, 1972, the first long life amateur satellite was orbited. This satellite, OSCAR 6, has provided many new aspects to DX chasing. In mid-November, 1974, a second long life satellite, OSCAR 7, was orbited. It has provided even more DXing activities.

OSCAR 6 contains a 2 to 10 meter transponder with a 100 kHz bandwidth. Specifically, the input frequencies are 145.90 to 146.00 MHz, which translates to 29.450 to 29.550 MHz respectively. For normal communications, a power of approximately 100 Watts effective radiated power (ERP) provides a satisfactory return signal on the 10 meter downlink. For DX chasing, one should be able to access the satellite when it is near the horizon; to be consistent, an ERP of 1 kW is recommended. To keep the AMSAT officials happy and prevent overload of the satellite's receiver, one should adjust his ERP to maintain a reasonable but not strong return signal (comparable to other signals). Effective radiated power is defined as: matched power at the antenna terminal(s) times the antenna gain as a ratio. For example, consider an antenna with 12.5 dB of gain; this relates to a power ratio of 17.78. If the power at the antenna terminals was 100 Watts, the ERP would be 1778 Watts.

OSCAR 7 has two transponders. The first is similar to OSCAR 6 – this is termed Mode A. Its input frequencies are 145.850 to 145.950 MHz, translating to 29.400 to 29.500 MHz output. The second is a 432 to 145 MHz repeater – it is termed Mode B. Its frequencies are a 432.130 - 432.170 input, translating to a 145.970 to 145.930 output. There is an inversion in this transponder – as the operating frequency is increased, the output frequency decreases. This was done intentionally to reduce the effects of Doppler shift. Also, because of the inversion, a USB uplink (input)

Fig. 1. OSCAR 6 and 7 tracking data for Washington DC and vicinity. (-) = west longitude; time = after ascending node equator crossing.

signal becomes an LSB on the downlink (output).

For OSCAR 7, Mode A, a somewhat higher ERP is needed than with OSCAR 6. A good value is 10 dB more or 1 to 10 kW ERP. For Mode B, an ERP of 80-100 Watts will provide an excellent return signal.

Both OSCAR 6 and 7 are termed to be in sun-synchronous orbit — that is, they are available for communications at every point on the earth at the same local time of day. Each satellite is fixed in a near polar orbit approximately 900 miles above Earth. With such an altitude, it is possible to communicate with the satellite when it is 2450 miles away from your location. This yields a maximum communications range of 4900 miles. This can be extended considerably at times due to peculiar propagation phenomena which will be discussed later.

Probably the most exciting facet of DXing via satellite is that you can operate every day and not be concerned with normal HF ionospheric problems. Once the satellite is within your range, you are ready. There are occasional VHF/UHF propagation disturbances which do affect communications, but not to the extent that a solar storm would have upon HF. An example: Last spring when HF communications were almost totally wiped out by a storm, many Europeans were worked via satellite.

Operating

In order to operate via the satellite, one must know when it is available and in what mode it will be for a given day. Orbital data is available from many sources. Probably the most convenient source is the W6PAJ handbook. This book is published yearly and contains all revolutions for OSCAR 6 and 7*. The data is published in the form of date (GMT), revolution number, time (GMT) that the satellite crosses the equator in an ascending node (south to north) and the longitude in degrees west of Greenwich. With this data, one can compute when the satellite will be within his particular window.

The next problem is where to point the antenna. Unfortunately, this is difficult to accurately describe in a few words. Obviously it would be far easier to use a high power transmitter and almost non-directional antenna, thus eliminating the need for antenna directional data. Sad to say, high power equipment is rare and expensive.

Generally, for ascending node revolutions, the satellite will rise from the south to southeast and go east of your QTH and leave in northwestern azimuth. If the longitudinal crossing is west of your longitude, then instead of passing to the east, it will pass to the west.

This is fine for azimuth, but what about elevation? In most cases the operator will not be interested in elevation, because he is only interested in DX which can be worked principally when the satellite is near the horizon. The only reason for a DXer to use an elevation mount is to achieve practice in satellite usage and communicate with nearby amateurs.

When OSCAR 6 was first launched, the VK amateurs generated AZ/EL data based on longitudinal crossing for many major cities in the world. I personally use this table for my antenna pointing. The second feature of the table is that it defines the satellite coverage for a particular QTH. An example of this information for the Washington area is given in Fig. 1.

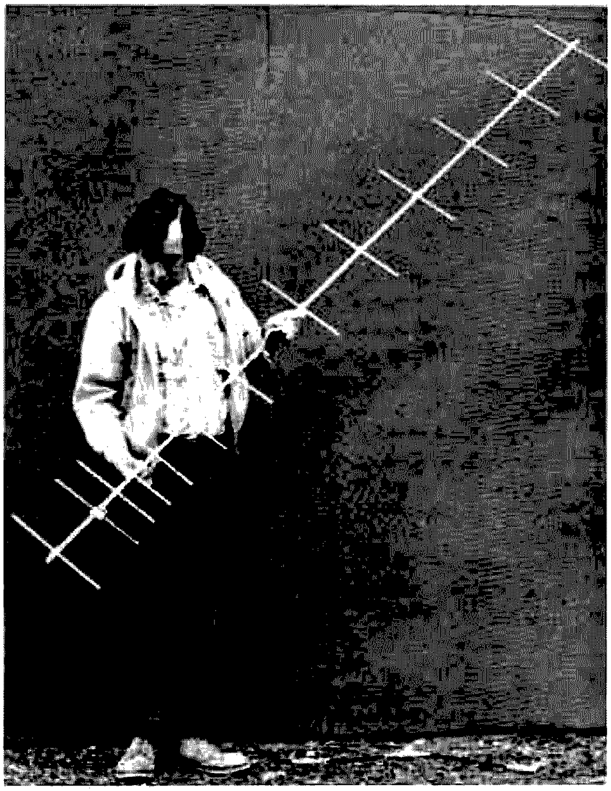
To generate this data, a computer program (written in Fortran IV and adaptable to most machines), is available.

Operating Tips for the Beginner

There are several very important techniques that will be helpful.

Pick an input/output frequency combination to which you can repeatedly reset your equipment, and always start

*Skip Reymann W6PAJ, PO Box 374, San Dimas CA 91773. For 1977 handbook send $5.00 non-AMSAT members; $3.00 AMSAT members and a self-addressed sticky label.



W3TMZ and his home brew 14 element KLM 432.

operating from that frequency. This technique is quite valuable for the following reasons. To find your own downlink signal at the beginning of a pass, you will always know where to expect your signal (± 1 kHz). Once you find your downlink signal, then you can QSY in increments – if you get lost, you can always return to your reference frequency plus Doppler and start over. Believe me, this happens, and this technique works.

On OSCAR 6 and 7, Mode A, it is not unusual to actually be accessing the satellite, but, due to a number of phenomena which are not clearly understood, you may not hear your own return signal. I have worked quite a bit of DX without hearing my own signal.

During my initial contact on OSCAR 7, Mode B, I was unable to hear my own signal because of downlink receiver desensing. Every time I keyed the transmitter I wiped out my receiver and, therefore, could not find my signal. I did not know whether I was getting into the satellite or not, but, by calling CQ repeatedly and tuning the satellite passband, I finally heard W2GN answering my CQ (this is actually poor practice) and now had a reference set of frequencies.

The Art of DXing via Satellite

For working DX alone, it is best to limit your antenna systems to low elevation angles. Concentrate as much energy (within reason) at the satellite so that as soon as it comes into range you have a workable signal. As has been mentioned previously, do not count on always hearing your signal. Sometimes it just isn't there, but others can hear you. To really work super DX via space is similar to 20 meters – you must use or try any tricks that seem reasonable. A technique for working a specified area is to use a high gain antenna(s) positioned at the midpoint of the satellite's ground track. This is a technique that was used to work KH6 from this area. The same technique could be used to attempt to work a UA9.

At some frequencies (28 MHz and above), another interesting phenomena can occur – signal ducting. This is best described by example.

I have heard OSCAR 6 when it was over Eastern Russia heading for the North Pole with excellent signals. This particular pass was quite removed from my normal window.

On several occasions, WA4JID (Ft. Lauderdale, Florida) has had an excellent return signal from OSCAR 6 when the satellite was out beyond KH6 traveling toward ZL. Actually he had acquisition for a period of 7 minutes after his normal loss of signal (LOS) time. There was no one to work, so he called CQ. Finally he dropped out and the next signal he heard was ZL1WB calling CQ on his frequency. WA4JID uses .35 Watts to a 10 element cross-polarized antenna.

ZK1DX regularly hears OSCAR 6 when it is over the East Coast of the U.S.

Based on these observations, it appears highly possible that one could QSO a ZL from Southern latitudes. I believe with a kW, some antenna gain and good CW operating, it would be possible to really stretch the normal communication ranges.

In this regard, I do not believe that OSCAR 7, Mode B, is as easily stretched. The received signals just seem to drop when predicted LOS occurs. I can state that the downlink received signals on Mode B are much better than what one will hear on 28 MHz. An example of this is hearing OA8V with his 10 Watt ERP with a beautiful signal.

Equipment and Antennas

The equipment required to work OSCAR 6 and 7A is some type of 2 meter transmitter and a 10 meter receiver. A good preamplifier for 10 meters will help immensely. Almost anything will work as the transmitter as long as the particular operator is satisfied with its performance. Here are several ideas for equipment that will work:

1. An FM transmitter with provisions for keying installed and control of normal T/R relay (you do not want the relay to follow your keying or you will soon need to replace the relay). Note: Do not use FM for communications via the satellites.
2. A GE/Motorola FM transmit (TX) strip adapted for CW.
3. VHF Engineering TX-150 strip.
4. Homemade/commercial transverter and amplifier.
5. Two meter CW/SSB transceiver and amplifier.

For OSCAR 7, Mode B, the equipment required is somewhat more difficult to obtain. For the downlink, a reasonable 2 meter converter for an HF receiver will do quite well as will almost any of the present multimode 2 meter transceivers.

The uplink transmitter availability is somewhat limited. Several ideas for equipment include:

1. GE/Motorola 450 FM strip converted for CW.
2. Tripler for a 2 meter transmitter.
3. Homemade/commercial transverter and amplifier.
4. Commercial 432 MHz CW/SSB transceiver.
5. GE/Motorola FM strip converted to be a high mixer/amplifier (SSB/CW).

Further information on equipment requirements is given in the reference section at the end of this article.

With respect to antennas, almost anything will work to some degree or another, but remember that the satellite requires a minimum ERP and the antenna for most low power transmitters is quite important. There are several general rules concerning good satellite antenna practice.

Antennas do not need to be particularly high. For

DXing, what is important is that they be high enough to be in the clear.

The antenna feedline loss becomes an ever increasing factor in VHF/UHF satellite operations. As the antenna height is raised, so is the amount of feedline, preferably coax. At VHF/UHF RG-8 is ok, but, for example, at 146 MHz, 100 feet of RG-8 will have a loss of 3 dB (including connectors). This 3 dB loss reduces the ERP to half of what there would have been if the feedline were lossless. At 432 MHz, 100 feet of RG-8 has 5 dB of loss.

For 28 MHz, it is best to use two antennas, a beam pointed at the satellite (which need not be elevated), and a vertical (I use a vertical dipole). As the downlink signal fades, I switch from one to the other and vice versa.

For 146 MHz, I prefer linear polarization. For DX, I use vertical polarization, and for the remainder I use horizontal. Circular polarization works quite well, but I don't like it on the horizon due to losing half my ERP in the opposite polarization. Circular will have less fading, but for DXing the fading is minimal and can be tolerated.

For 432 MHz, the antenna situation becomes a little sticky – the size of the antenna is small but the chance for error in home built antennas is much greater. I recommend using standard proven antennas. Beware: Some antennas on 432 simply do not have the gain that is advertised. Basically a 6 to 16 element yagi will be adequate. But, remember, the larger the antenna, the sharper the beamwidth, thus requiring accurate pointing. Conversely, as the antenna size is reduced, so is its gain, and thereby the ERP.

In summary, a balance or compromise must be achieved in transmitter power, feedline and antenna size versus pointing problems to obtain the performance that is desired.

Various Amateurs' DX Accomplishments

First of all, I am sure that there are sufficient unique DX accomplishments by a number of individuals that we could go on for some time. To mention a few – when a new country comes on via satellite, you can bet that W2BXA will be in there as if it were a "new one" for him for the DXCC Honor Roll. W8DX, W1NU, K1HTV, W1FTX, VE3SAT and a number of the Northern Jersey DX club members have worked over 50 plus countries. Many have worked 5 continents from the US. Asia is the most difficult.

Conclusion

Many amateurs, who have for years chased DX on the HF bands, have recently started working DX on the satellites and found it to be every bit as challenging. Perhaps you too would like to join many of the HF DXers on OSCAR 6 and 7? If so, it is hoped that many of the ideas in this article will help you along to your fifty states via satellite or maybe even fifty countries. ■

LETTERS

from page 48

single person much more than "I".

I have never referred to myself as "we" and I have discussed this with ham friends, who generally agree that "we" is used only by hams who have a Lindberg complex; they seem to try to create the impression that they never use it in this way, but the very next time I hear them on the air, they are referring to themselves as "we."

All this is somewhat confusing to me and the purpose of this letter is to locate someone who can tell me why this is done, how it got started, and, if there is no logical reason for its use, why do hams continue to use it?

Just as a parting shot, why don't hams on voice just laugh instead of saying "hi"?

Keep the good work going, Wayne; you have a forty over nine magazine.

SCI-FI

Several months ago I sent you a note which requested hams who read science fiction to write me. You printed it in the Ham Help column. For that I thank you very much. I received a number of replies and have come up with some more information. I would appreciate it if you would print it as a follow-up.

7250-7255 kHz have been designated as calling frequencies for hams who want to discuss science fiction. 7250 will be used in the evenings, and 14310 can be used on weekends daytime. This will not be a net or any type of directed operation; rather, it will be simply a gathering frequency for interested persons. Just get on and holler "CQ SF!"

For any other information, write me at the following address.

OSCAR Frequency Relationships

-- now, where is my downlink?

Robert H. Main W1ZAW
Bible Hill Rd.
Hillsboro NH 03244

One of the most difficult things to get a handle on when you first start out on OSCAR is the relationship between uplink and downlink frequencies. Ever hear a signal on 29.440 MHz and wonder what frequency you should be transmitting on? You look for your hand calculator,

UP DOWN

only to find that it is on your desk at work. So you have to take pencil in hand and try to find some paper to figure things out. By the time all that has been accomplished, either the satellite has flown over, the station you were hearing is talking to someone else, or the station is out of range.

Having had that experience too many times, I decided it was time to have some printouts at my fingertips, or on the wall next to my operating location. So, with the help of a computer, the accompanying tables have been developed. As you can see, OSCAR 7 users (mode B) would really have a calculating problem tripling up from 2m. It's a simple matter to use the desired listening frequency and follow across the chart to find the desired transmitting frequency. We carried this out to five places so that anyone rockbound could order crystals easily. Also, the telemetry fix on board OSCAR 7 has been putting out a good signal and is an excellent way of

checking your receiver.

By the way, don't forget the Doppler effect which causes the satellite to gradually shift in frequency as the bird moves toward or away from your location. But Doppler effect or not, the relationship between the various uplink and downlink freqencies will remain consistent. ■

Calculate OSCAR Orbits

-- with your HP-25 calculator

Last year I developed an interest in OSCAR activity after having read a back issue of *73* that was entirely devoted to this subject. When I sat down to work out the orbital times to look for 06 and 07 in my area, I decided very quickly there had to be a better way. The calculation of orbit #5, for example, on any given day can be a time-consuming effort at best, and, if you want the most likely times for communication via this mode on a daily basis throughout the month, these calculations could be a downright nuisance unless you have access to a complete list of tables for this purpose.

Since my HP-25 was sitting idle and I was still trying to justify its purchase price, I decided that it was about time it should start doing more than calculating debits from my savings account.

This program is not very complicated in the sense that it doesn't work out any heavy math problems, but it does do the job of working out the orbits of either 06 or 07 between the times listed each month in *73*. The program will update the orbital number, the equatorial crossing and time of crossing for each successive pass from the first pass listed for each day. If you wish, subtracting the number of hours you are from GMT on the first entry will result in a local time readout for the equatorial crossing.

An example is probably worth a thousand words, so let's take the case of orbit #19264 on January 1, 1977, for OSCAR 6. (See Table 1.) My QTH is eight hours from GMT; therefore, subtracting 8 hours from 0124:02 and adding 24, we arrive at 1724:02 local time. This, of course, is the day before or 5:24 pm on December 31.

Table 1.

Key in the program information using the HP program forms. When the program is run, the pause will give the pass number, and the first stop will give the time. Pressing the R/S key will then give the equatorial crossing longitude for this orbit. The drawback to this program is that you have to go through each pass to reach the one you want, but, unfortunately, I haven't figured out how to get an extra register and 30 more program steps into the calculator in order to eliminate this problem, so I guess this will have to do until I can get my Micro P operational. (See Table 2.)

Hopefully this article will encourage other members of the ham community with access to one of these calculators to sit down and work out additional programs for this and other areas of our hobby. If this is the case, I will be looking forward to seeing these programs in future issues of *73*. ■

Corrections

Texas legal beagles and scanner manners have indicted us for stating that the "Big Bust In Amarillo" (Oct., p. 154) took place on July 7th. We throw ourselves on the mercy of the readership, and readily admit that the date was, indeed, July 6th. No more letters, please.

I think I've found an error on page 47 of your August issue. The diagram for the Zeppy Vertical shows the braid of the coax attached to the radiator and the center conductor to the matching stub. These connections should be reversed. As written, the antenna was inferior to a ¼ wave whip. Reversed, it improved on the ¼ wave by several S-units. Keep up the good magazine.

Tim Knauer WD9AMY
Peoria IL

In addition to my new call and address, please note several minor changes to "Synthesize Yourself!" (Oct., p. 182):

1. Page 186, col. 4, lines 16 and 17, should read, "nect the square wave *input* from pin 1 of the MC*4044*,".
2. Page 186, col. 4, line 32, should read, "MC*4044* as shown. The out-".
3. Page 188, col. 4, lines 36 through 38, should read, "generates a square *wave* output. In cases where the vco generates sine waves *or* other wave-".

Ham Help

I have been interested in ham radio for the past couple of years. I currently hold a Citizens Band license, but I am totally disenchanted with that type of communication. I have been studying on my own and have no trouble with the technical aspect of the license. But the code has been very disheartening. I would like to know if there are any clubs that give Morse code classes in my area. Or if I could meet or contact amateur radio operators who would be willing to help. Any and all help will be deeply appreciated.

Box 490
Union City NJ 07087

Help! I purchased a Hallicrafters Tornado SR-500 SSB 500 Watt 80-40-20 rig and need help finding someone who carries the 8236 final amplifiers. Can't find listing in Sylvania, RCA, Amperex, or other tube makers. Where can you get these 8236s and what is their cost (understand Hallicrafters is no longer in business)?

Also, if anyone has information on modifications, improvements, changes, etc., to the SR-500, I would appreciate their writing to me. Can the 8236s be subbed for (for example, with a pair of 6146Bs with only 200 Watts PEP instead of 500 Watts)?

Any assistance from other hams would be appreciated. Thanks.

Marvin Jack Moss W4UXJ
P.O. Box 28601
Atlanta GA 30328

With the ever-increasing use of electronics in hospitals and related health care facilities, there has been a large influx of EE and E Techs to provide repair and calibration for the medical electronic equipment that lies scattered throughout these establishments. It is my guess there must be several hundred amateur radio operators hidden within these ranks. With the help of your column, I would like to compile a listing of all licensed amateur radio operators employed by hospitals/health care facilities/medical electronic equipment manufacturers and service centers.

Interested hams should send their name/callsign/QTH to my attention.

Help! I am looking for manuals for the following low band radios: Motorola Model L41G-1A — this is an ac base; Motorola Model T71-GKT 1100B — low band 12 V dc mobile. If anyone has manuals or schematics for the radios, a copy would be appreciated. Please drop me a line.

CB to OSCAR

-- from 10 to the sky!

This article describes how to convert a specific 23 CB radio for use on the OSCAR satellites and gives you my ideas on an OSCAR 10 meter bandplan very much like that of W4NVH in the May, 1977, issue of *73 Magazine*, p. 106. (He covered the 28 MHz portion of 10 meters, but used the same channel and conversion of CB gear principles.) If you read that article, you will see that the method applies very nicely to many of the now very inexpensive 23 channel CB rigs. The more I read W4NVH's article, the more things I could find that directly applied to the Sears 23 chanhel Model 934.36740500 CB I already had.

The CB channels have a few blanks between the 23 channels (remote control, etc.) that are taken care of by one each of the transmitter offset oscillator crystals and receiver offset oscillator crystals. In my transmitter, the crystal frequencies of 10.595, 10.615, 10.625, and 10.635 MHz are used, and, in the receiver, 10.140, 10.160, 10.170, and 10.180 MHz are used. Following a numbers progression, the oddballs are obviously the 10.595 and 10.140 crystals. In order to maintain continuous coverage, I changed the 10.595 to 10.605 MHz and the 10.140 to 10.150 MHz. Then I had a synthesis scheme capable of 230 kHz coverage in 10 kHz steps.

Considering that the OSCAR 6 and OSCAR 7 combined bandwidth is only 150 kHz, and further considering that an AM or AM/SSB mode (even when CW keying is added) would not be at all welcome above 146.000 MHz, my bandplan starts at 146 MHz and works downward. A couple of unique quirks came out of that fact. They alone might add merit to the bandplan, when using CB radios. The first is that, when you convert a CB radio over to the 10 meter band for transmit and receive, two things happen. The receiver winds up being in the 10 meter downlink, where it belongs, by only changing crystals and repeaking a very few front end stages (on signal, if need be — for those of you with little building experience and test equipment).

On transmit, the transmitter signal output is on 10 meters to go to the upconverter, and, believe me, just about every commercially made transverter uses a 10 meter input. I know, because I have spent two years trying to find a Drake TC-2 to go with my Drake TR-6 to get up to 2 meters. Unfortunately, the Drakes run a 14 MHz i-f out of the TR-6 and into the TC-2, negating using anything but Drake's TC-2. Couple this to very few TC-2s having been made at all (that's when Drake dumped their VHF line altogether, leaving us at the mercy of imports), and you can appreciate my problem.

Another transmitter benefit is that the transverter winds up being 116.45 MHz — exactly the OSCAR offset through the translator in reverse. So, when you tune the receiver, you are tracking the transmitter right along with you, plus or minus Doppler. As for Doppler, the CB manufacturers never could get together to decide on what channel they were transmitting or who was on the channel frequency and who was off. So, manufacturers include a little control on most panels now, marked ± delta - i.e., a Doppler control.

As for the bandplan, if you begin at 146 MHz as the 29.55 MHz downlink (or 146 MHz uplink), the cardinal frequencies of 29.5 MHz and 29.4 MHz (OSCAR 7 band edges) just happen to fall on channel 19 and channel 9 respectively.

Plug in the new synthesizer crystals X-1 to X-6 and change the offset crystals X-10 and X-14 to pull the band together. Then peak up the synthesizer output tank (T8 in mine). C37, across the primary in the Sears, may have to be reduced in capacity slightly, if the synthesizer output transformer lacks enough tuning range. Now, with the new synthesized frequencies from 39.955 to 40.155 MHz coming out of the synthesizer, feed a 10 meter signal (signal generator or off air) into the coax fitting. Align the 10 meter (was 27 MHz) front end receiver coil(s), which are T1 and T2 in mine, by backing out the slugs a bit and tuning for maximum agc, signal, etc. Do *not* touch any other receiver tuning, assuming the rig is new and/or properly aligned for CB frequencies. The i-fs do *not* change. For CW reception, the easiest way is build a little 455 kHz vco, so you can "pot" control it with dc from outside the radio and not botch things up by drilling holes in the panels. Assuming you like channelized transceiving as little as I do, you can build a second

New Channel	Freq.	Equiv. 2m Freq. + 116.45	Synthesizer	Transmit osc.	Receive osc.	Note

Table 1. CB radios to OSCAR bandplan for a Sears 934.36740500. All figures in MHz. Xmit: Fsynth - Fxmit osc = four MHz; Rcv: Fsynth - Fin - Frcv osc = .455 MHz Lo i-f.

vco on the synthesizer frequency, or some submultiple of it and multiply, and run it, too, from an outside pot. After all, it is no longer a CB radio, so vfo/vcos are legal. In my own, I kept the crystals in the X-3, X-4, X-5, and X-6 positions (but at the new frequencies shown), and a vco runs into the X-1 position, with X-2 a blank. This way you can run the vco from 39.955 MHz to 40.155 MHz using a ten-turn pot for vernier action and, by switching from channel 1 through 4 positions, cover the entire 29.32 to 29.55 MHz range on receive and have the proper transmitter frequencies to upconvert to 145.77 to 146 MHz. With the lower edge below OSCAR, you are about in 2 meter AM land. With the same synthesizer schemes used by so many rigs, even an AM/SSB (23 channel version) is cheaper now and would really be a great way to go, if you want the SSB mode through OSCAR and can afford an extra few bucks. By allowing the vco to tune down to 38.185 MHz (or shifting it to cover 230 kHz there, as 39.185 to 39.405 MHz – with a small C switched in?), you can have a dandy 145 to 145.230 MHz out of the transverter and be right with the 2 meter SSB gang. Add a small 2 meter to 10 meter converter (Hamtronics makes a great one), using the same 116.45 MHz oscillator offset, and you have a rig as versatile as the most expensive ones designed for OSCAR and 2 meter gear on the market.

The transmitter conversion is just about as tough as the receiver – in other words, not at all. In mine, once the receiver was done (hence, the synthesizer), it involved peaking up the old 27 MHz transmitter stages to the 10 meter band by backing out the slugs a little and, where needed, reducing the tuning capacitors across the transformers, when the slug had to be backed out too far to be practical (slug showing out of the coil form). In my radio this involves T12-C69, T13, T14-C72, T15-C77, T16-114, T17, and T18. This is as easy as tuning up the average Heathkit for the same reasons, because the test equipment is built in the form of a built-in wattmeter (rf output) and swr combination meter function in transmit. Incidentally, when I said peak the receiver for maximum agc on an incoming steady signal, I had an S-meter in my radio to measure that by.

In the extraneous department, the rig I have has a noise limiter that works pretty well as is, so I left that alone. It also has a PA position that can be put to good use. Since mine is an AM only rig, I had only CW in mind. The modulator-audio stages in the transmit mode (they are shared) can be put to use by placing them in PA (which routes the audio to that jack from the receiver as well) and then causing the low audio stages to be an oscillator at some pleasant tone. Or you could use a separate tone oscillator, so that when you key the rig, you have sidetone. On the AM only rigs you might as well, because AM is not very welcome through OSCAR because of its unnecessary BW.

On the subject of keying, since this is an AM rig only, the + voltage for the modulation is broken away from the modulation winding of the common audio transformer by removing an isolation diode (D13) and opening that path. The + voltage from the power supply section is routed out to the external speaker jack, after taking it out of the receiver audio output path and putting a permanent ground on the low side of the speaker.

While on the subject of the speaker, I had a problem with mine. There is a 10 Ohm resistor in series with the 8 Ohm speaker, whose only purpose I can see is to allow them to run one common audio circuit, transformer, and a lower wattage speaker, and to accept the lower audio output on the bottom-of-the-line sets. This was a 1 W 3-inch round unit in my radio, and it was shorted, to boot.

Part of the reason I got the radio for the right price was that it did not work. It had one open copper foil in the +V copper, where the shorted speaker had tried to make a fuse out of it – and it succeeded. That is absolutely all that was wrong, and I ran it as a base by sharing my Heathkit supply for the HW 202 FM for months before I tried working on it. I got mine for less than $10, so check your local sources.

Back to the speaker – when I replaced it, I got a 3-inch round, 2 W replacement speaker and stuffed a small, 2 Ohm ½ W resistor in the 10 Ohm spot. I can now drive you out of the room with audio!

When you plug a key in the external speaker jack now, the key opens and closes the driver and final + voltages, and you have a CW rig – almost. The microphone circuit in my model is rather tricky, as it does all the changeover (X/R) by voltage switching. I substituted another DPDT switch – toggle type – on the same panel as the vco synthesizer and vco/bfo pots, and used it for the transmit position. Leave the microphone and connections off the switch and wire the rest the same, just to be rid of the PTT/hold-the-button-down routine.

When the key is depressed, the LED modulation light comes on, as it is activated by the same power line as the driver and final. It makes a good CW monitor, if you like the visual types and don't want to add the tone oscillator into the audio circuits.

To get the vco lines in and out of the radio, mine had a Heyco type grommet that "bites" the +12 V and ground where it goes into the back panel through a 3/8" hole. Replace it with a normal 3/8" rubber grommet, and you have a hole you can drive a bus through, with plenty of room for 6 to 8 wires.

Convince your CB "good buddy" that he really needs SSB or 40 channels, and offer him a good trade price for his old 23 channel rig. The dealers are offering peanuts on 23 channel rigs, because you can buy a new 23 channel so cheaply now that they can't sell a used one. He will end up happy and so will you! Or, go see your local CB store, and see if he took the same bath most dealers and wholesalers took, when they were stuck with warehouses of 23 channel stock, when 40 channel hit the market. Talk it up at your club (and the bandplan and see if they agree), and then go make an offer on 10 or more identical units – quantity talks. They are great for CD type groups in crowded 2 meter FM areas!

Last, but certainly not least, if you are the least bit adept at repair work and common logic and own just a VOM or VTVM, you can buy a non-working unit from places like Sears Save Shop and local radio dealers who don't really have much in the way of repair facilities.

Well, I've given you a plan of attack, a bandplan so you will have company in the present wasteland of 10 meters, a cheap way to get up on OSCAR, some hints for using my unit, and the source for one of your own if you go looking. Even schematics and manuals are a breeze (unlike the old FM conversion days when *any* Motorola manual or even a close schematic you saw as a ham was yellowed, battered, torn, thumbprinted, and worn from the use of 50-plus hams).

You should know that T18, in my rig, is used to adjust the output to 5 Watts and also that the final device used is a 2SC799 with a 10 W hfe of 50 to 90, 150 MHz rating with a BVcbo = 80 V, BVebo = 5 V, and BV well above the rated use! Consider the low duty cycle of CW versus the AM cycle which it was running a steady 5 Watts at. I run mine off the high regulated 18 V dc and load it up (tune) for about 14 W key down. I haven't lost a device yet, but, to be safe, you may want to quit at the manufacturer's (Nippon Electric) rated 10 Watts.

There are only two words of caution I will add in closing. If you tackle a PLL type synthesizer, it's not so easy. It can be done – on some -- at some time and expense and risk of odd products sneaking out.

My only other comment is that you should turn back a few issues and read through W4NVH's article. It is excellent background and easy to follow and use. You can figure out just what kind of rig you have, if you already have it, and how to apply my antics to it.

Don't try to part-convert one to cover 10 meters (say, low end, per W4NVH) for CD activity and try to save a chosen "few" of the CB channels for CB use. You void the manufacturer's approval when you cut into the rig, even if you hold a 1st class radiotelephone license, as I do. You void any warranty on the rig any way you cut it. And you could just void your license if you get caught with this modification. Pick your band, and have fun. ■

Fig. 1. Two stations must "see" the satellite's transponder simultaneously in order to communicate with each other, i.e., they both must be located in the area "illuminated" by the satellite. Note that a transponder located on the moon will allow communication with stations separated farther apart than a satellite orbiting the Earth at lower altitude.

Track OSCAR 8!

-- step-by-step method

The launching of the AMSAT OSCAR 6 and 7 satellites gave amateur radio a permanent foothold in space communication. In years to come, satellite communications will become as common as 2m FM or DXing on 20m is today.

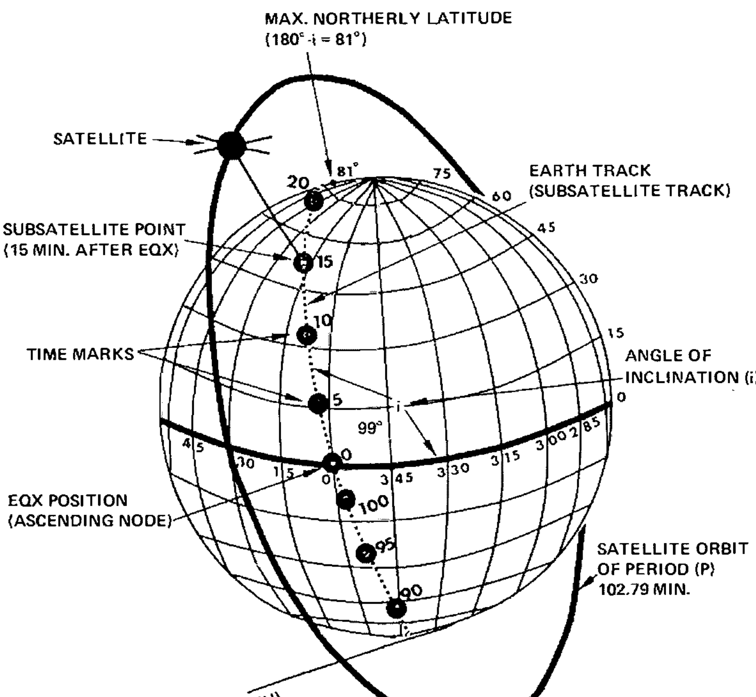

Fig. 2. Model of orbiting satellite (static Earth).

Although there are now thousands of users of OSCARs 6 and 7, they represent only a very small fraction of the total amateur community. Why is it that so many VHFers who own perfectly suitable equipment never worked through OSCARs?

Apparently, the major deterrent is the lack of familiarity with satellite tracking, which many consider to be a formidable and complex problem requiring knowledge of astronomy, astrophysics, higher mathematics, and other disciplines of science. But, in fact, satellite tracking is a relatively simple procedure easily grasped by those who show even a slight interest in this subject.

The purpose of this article is to explain the procedure of satellite tracking from the standpoint of common sense and simple reasoning. I suggest that the reader follow

the presented sequence of reasoning step by step and not go to the next paragraph before the previous one is fully understood.

Space communication is the future of amateur radio. We might as well get familiar with it, and the knowledge of satellite tracking is the first step.

The First Earth Satellite — The Moon

Let's suppose that an OSCAR transponder was placed on the moon. Using suitable equipment, we could communicate through it the way we communicate via 2m repeaters. Since VHF waves don't bend around the curvature of the Earth, we may assume that the lunar transponder can be accessed only if the moon is above the horizon in respect to the stations that attempt to communicate through it. Obviously, a two-way QSO between distant stations can only take place if both stations have the moon in direct view.

Without any knowledge of astronomy, we can guess that at a particular instant of time the moon will be visible in different directions, and at different angles above the horizon, in different parts of the world. Also, there will be locations on the Earth where the moon will not be visible at all.

With the combination of the revolution of the Earth and the orbiting of the moon, the prediction of its exact celestial position, at a particular day and hour for a chosen geographical location, represents apparently a very complex problem. Nevertheless, this "difficulty" was solved thousands of years ago by ancient astronomers before trigonometry, calculus, computers, and even writing were invented.

The artificial satellites, such as the OSCARs, behave very much like a moon with the following small differences:

— Artificial satellites are too small to be visible to the naked eye, so their positions can only be predicted.
— They orbit the Earth at the rate of hours per revolution instead of weeks. This implies that their rising and setting at a particular location of the Earth will be more frequent.
— They orbit at low altitudes; therefore, the range from which two stations can "see" a satellite simultaneously will be much shorter (see Fig. 1).

Terminology

In order to better understand satellite tracking, we must form a three-dimensional mental picture of a satellite orbiting the Earth. A globe or any spherical object (even an orange) will greatly facilitate the comprehension of the subject.

In order to simplify the analysis of the orbital flight of the satellite, we are going to assume, for a while, that the Earth is *static*, i.e., it does *not* rotate on its axis. Once the static Earth concept is well understood, the introduction of the Earth's rotation, to complete the picture, will not present much difficulty. Fig. 2 shows a view of a satellite orbiting the static Earth. The orbit is circular.

At this time, familiarization with the principal parameters of orbital flight and related terminology is necessary because it will be used throughout the remainder of the article.

Orbit: The imaginary track of the path the satellite follows around the world. The plane of the orbit is fixed in space and is independent of the rotation of the Earth.

Altitude (H): The distance between the satellite and the surface of the Earth. For satellites in circular orbits, the altitude is virtually constant.

Period (P): The time it takes a satellite to make one full revolution around the Earth. The exact moment the satellite crosses the equator from south to north is used as a reference point. The period, therefore, is the time elapsed between two such equatorial crossings.

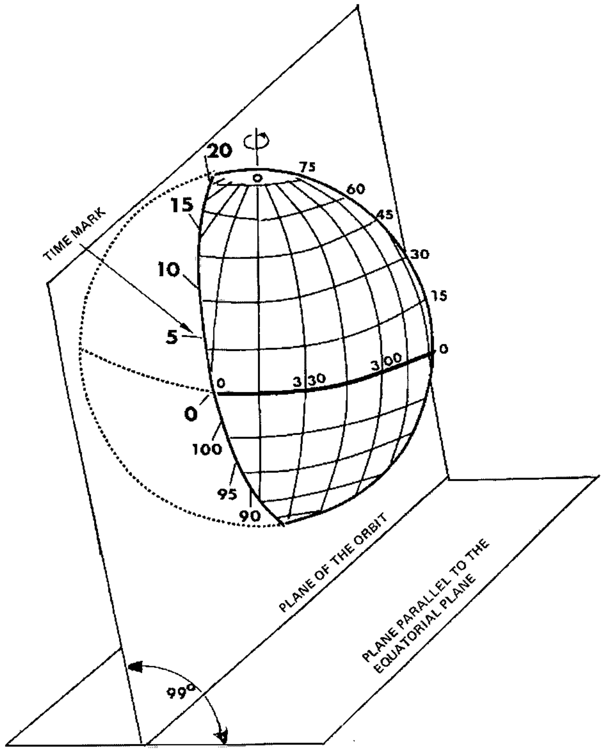

Fig. 3. Simulated Earth track on a plane inclined 99° from the equator (static Earth). Note that the orbital plane is fixed in space and the Earth rotates inside this plane from west to east (counterclockwise as viewed from a point above the North Pole).

Subsatellite Point: A point on the surface of the Earth where the satellite is directly overhead.

Ground Track (also Subsatellite Track): An imaginary path on the surface of the Earth consisting of all subsatellite points (during one period).

Inclination (i): The angle between the equator and the ground track (or the plane) of the satellite. It should be noted that this angle will remain constant through the entire life of the satellite and is not affected by the rotation of the Earth.

The angle of inclination determines the most northerly and most southerly latitude the ground track will ever reach. You may notice that even if the Earth is rotating on its axis, the ground track will never pass beyond a certain latitude.

Max. Lat. (N. or S.) = 180° - i
For OSCAR AO-D: i = 99°
Max. Lat. = 180° - 99° = 81° N. or S.

Equatorial Crossing Time (EQX Time): The exact time in UTC (GMT) at which the ground track crosses the equator from south to north. Knowing the exact EQX time of any orbit and the time of the period makes it easy to predict subsequent EQX times. We simply add the period (in minutes) to the exact time at which the previous EQX took place. In fact, the EQX prediction tables published by AMSAT and other amateur journals are derived this way.

In order to complete long-range prediction tables, the

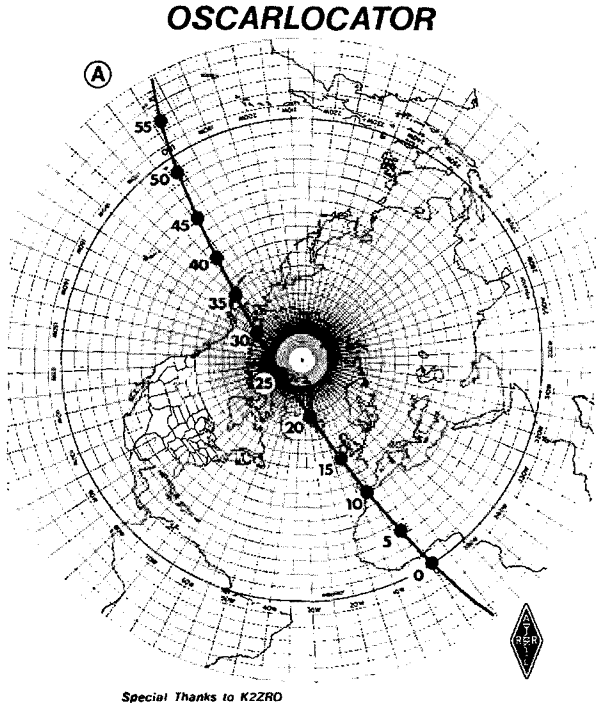

Fig. 4. Static Earth projection of the track of AO-D over the map of the Northern Hemisphere.

period must be known with great accuracy, because even small errors accumulate rapidly. (Example: Period of OSCAR 6 is 114.99441 min.; OSCAR 7 is 114.94513 min.)

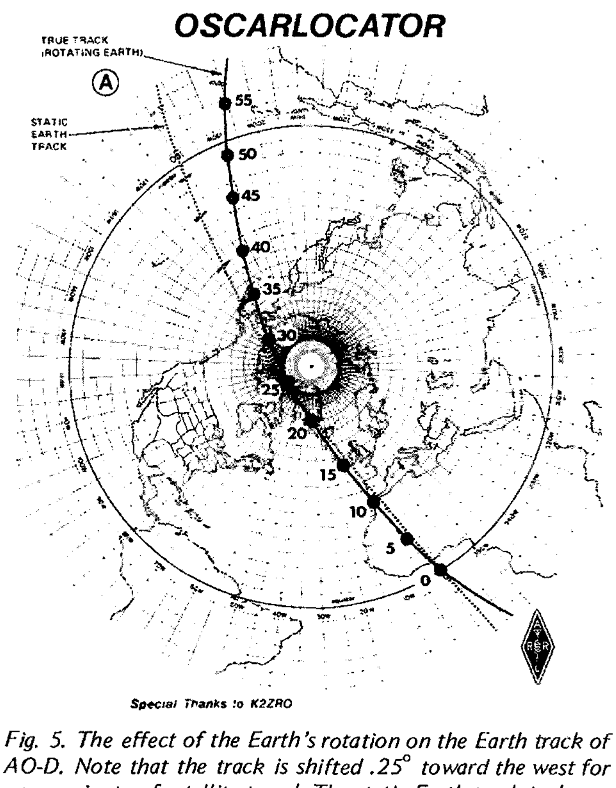

Fig. 5. The effect of the Earth's rotation on the Earth track of AO-D. Note that the track is shifted .25° toward the west for every minute of satellite travel. The static Earth track is shown as a dotted line.

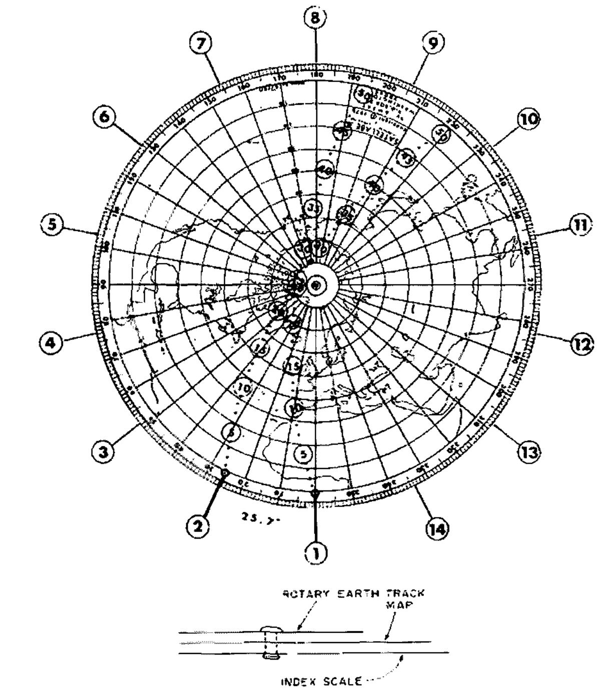

Fig. 6. Index scale. After setting the longitude of the EQX of the reference orbit, all longitudes of EQXs of successive orbits of the day can be predicted.

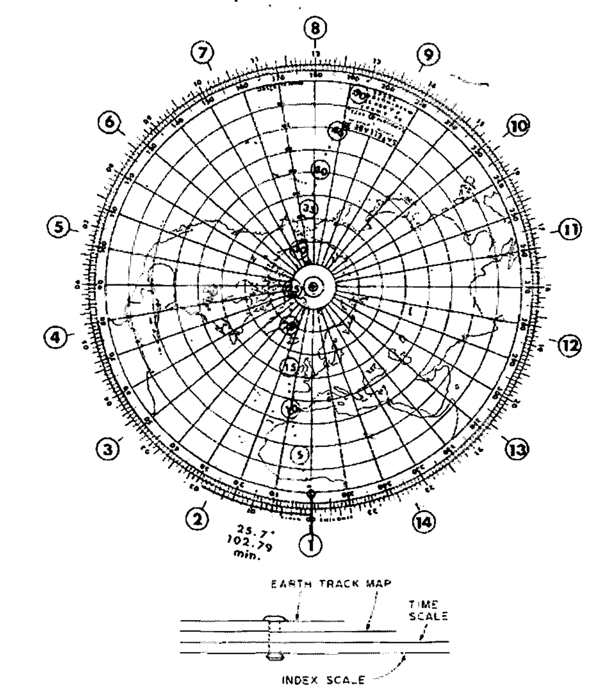

Fig. 7. Time scale. Setting the time of the EQX time of the reference orbit opposite index #1 allows prediction of EQX times of all consecutive orbits of that GMT day. Note that the Earth moving .25°/min. will rotate P x .25° during one period of the satellite, or 25.7° for AO-D. This corresponds to the index mark separation as shown in Fig. 6. Now, if the longitude and the time of the reference EQX are set against index mark #1, we can predict both time and longitude of subsequent EQXs of that GMT day.

Equatorial Crossing Longitude (EQX Lon.): The exact longitude on the equator at which a particular EQX, from south to north, takes place. Also called the "Ascending Node."

It will be shown later that subsequent EQX longitudes are separated by P/4 degrees. These figures are also used for long-range prediction of the EQX data.

Reference Orbit: The first orbit of a UTC (GMT) day, i.e., the first orbit that crosses the equator after 0000 UTC (GMT) from south to north.

Orbit Number: The count of the satellite's full revolutions around the Earth from the instant of the launching.

Reference Orbit Data: The date, orbit number, time, and longitude of EQX of a particular reference orbit. (Example: Mar. 17, 1978, 10526, 0012:24, 56.3°.)

Ascending Orbit or Pass: The part of the orbit when the satellite travels from south to north (over either the Southern or Northern Hemisphere).

Descending Orbit or Pass: The part of the orbit when the satellite travels from north to south. Note: The orbit will change from ascending to descending at the point where the ground track reaches its most northerly position (closest to the North Pole). The orbit will change from descending to ascending at the point where the ground track reaches its most southerly position (closest to the South Pole).

Ascending Node: The EQX position (longitude) during the ascending part of the orbit. It is often used as a reference point for orbital calculations (see Reference Orbit).

Descending Node: EQX position (longitude) during the descending part of the orbit.

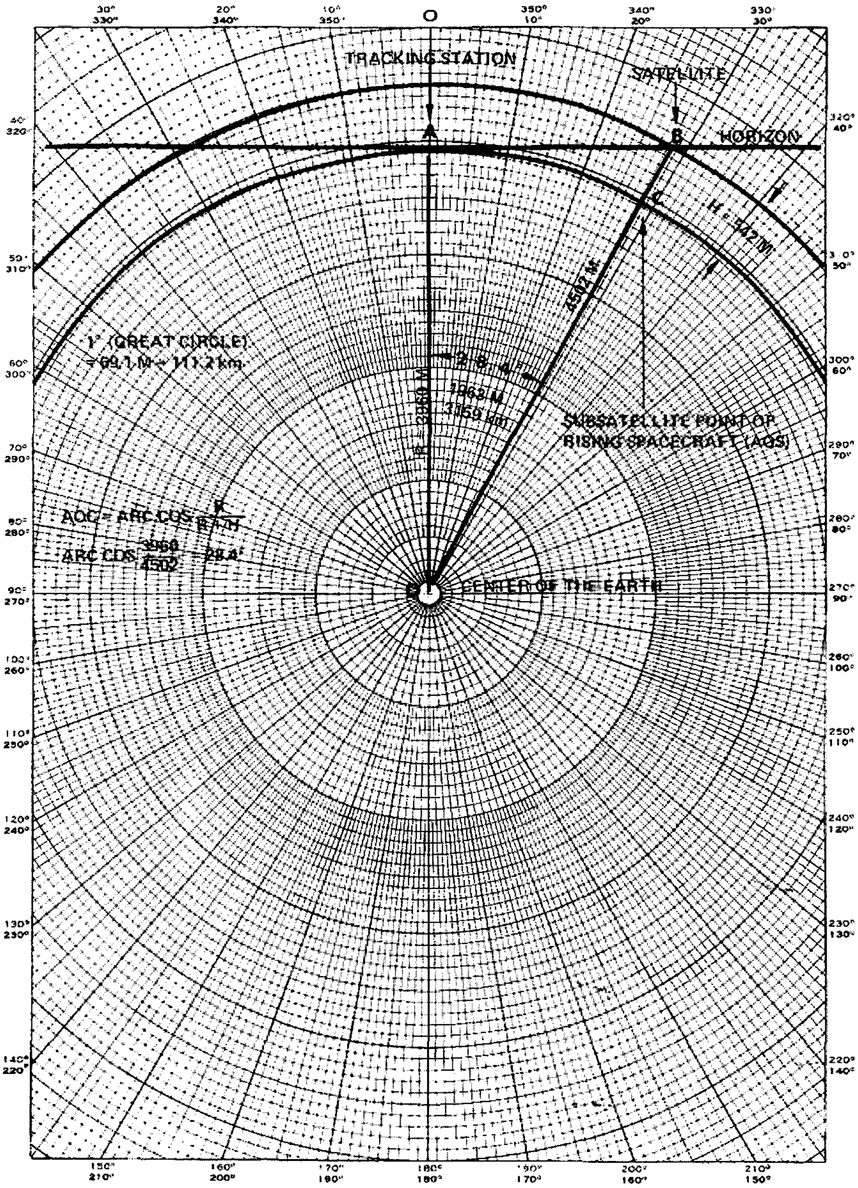

Fig. 8. Calculation of the distance from the tracking station at which the satellite enters the area of accessibility (acquisition of signal — AOS).

Developing the Ground Track on a Static Earth

As previously stated, we are going to assume at first that the Earth is static (non-rotating). The satellite is the proposed OSCAR AO-D with the following orbital parameters:

Period: P = 102.79 min.
Inclination: i = 99°
Average Altitude: H = 542 miles (872 km)

Examining Fig. 2 again, let's follow the ground track of the satellite.

Assuming the reference point to be of 0° longitude at the equator (ascending node), with the ground track inclined to 99° in respect to the equator, the satellite will follow the following path:

— Starts at 0° longitude at the equator (ascending node).

— Travels northward reaching the most northern latitude of 81° (180°-i).

— Begins descending and then crosses the equator at 180° longitude (descending node).

— Continues moving southward until it reaches the most southern latitude of -81°.

— Starts ascending and crosses the equator again at 0° longitude.

The total elapsed time of one such trip around the world would be equal to the period of the satellite, or ≈ 103 minutes.

If we would slice the globe at a 99° angle, in respect to the equator, and put both halves together again, the seam line would follow exactly the ground path of OSCAR AO-D on a static Earth.

Another way to visualize the Earth track is to cut a circular hole equal to the diameter of the globe in a sheet of stiff material and fit the sheet over the globe at an angle of 99° in respect to the

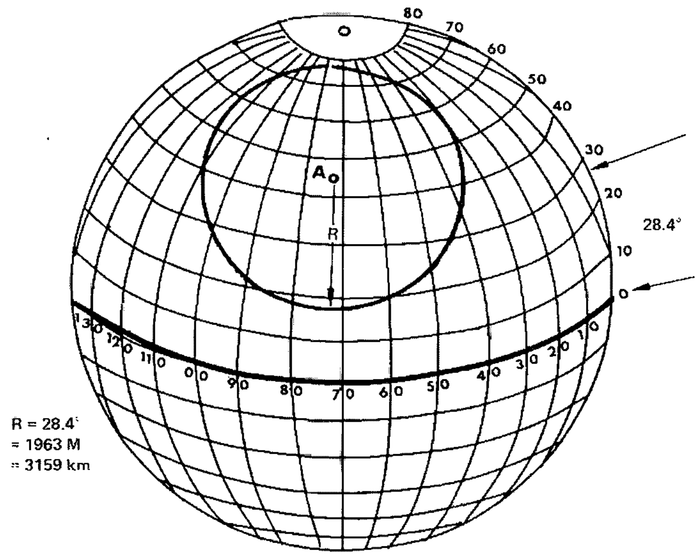

Fig. 9. Area of accessibility. The satellite will be available for communication when its subsatellite point is found inside the circle of accessibility.

equator, as shown in Fig. 3.

A satellite traveling in a circular orbit moves with a constant velocity. Consequently, all equal distances will be covered in equal increments of time.

The period of the AO-D is 103 minutes. Therefore, if we divide the entire length of the ground track into 103 equal segments, each segment would represent a distance traveled during a time interval of one minute.

In spite of its good accuracy, tracking of the satellite on a globe is rather cumbersome. A flat map is much more convenient for this purpose. Probably the best and most easily obtainable polar projection map suitable for satellite tracking is the OSCARLOCATOR, distributed and sold for just \$1 by the ARRL. This handy device can be adapted for tracking almost any satellite.

Let's now project the static Earth satellite track onto the map. Once the track is drawn on the globe, including the time marks, its coordinates, latitude and longitude at one minute intervals, can now be drawn at corresponding coordinates on the map as shown in Fig. 4.

If the track is traced on a separate piece of transparent material and pivoted on the North Pole, it can now be rotated to allow the start of its origin (Ø min. mark) at the longitude of any chosen equatorial crossing.

Setting an auxiliary clock to read ØØ minutes at the exact time of the equatorial crossing, we can now follow the progress of the satellite minute by minute. The time on the auxiliary clock will correspond to the time marks on the track that, in turn, will indicate the position of the satellite at that very time.

Table 1.

Obviously, tracking of the satellite on the static Earth is of little use. Therefore, we will now introduce the effect of the rotation of the Earth.

As mentioned previously, the plane of the orbit of the satellite is fixed in space, but the Earth rotates on its axis. As the Earth rotates, the ground track will no longer retrace itself during each orbit, but will be displaced .25° towards the west for every minute of satellite travel. The rationale is as follows:

– The Earth rotates on its axis from east to west (counterclockwise as viewed from a point above the North Pole).

– The Earth makes one full revolution of 360° in 24 hours or 1440 minutes.

– This corresponds to angular travel of 15° per hour (360 ÷ 24) or 1° in 4 minutes.

– In one minute, the Earth will rotate .25°.

Now, how will this affect the Earth track developed for the static Earth (Fig. 4)?

In Fig. 5, the static Earth track is drawn with a dotted line; the true Earth track (for the rotating Earth) is the solid line. You will notice that the true track is shifted .25° for every minute of satellite travel.

For example: 10 minutes after EQX, the true track will be shifted 2.5° west of the static Earth track; 20 minutes after EQX – 5°; 30 minutes after EQX – 7.5°; 51.4 minutes (half of the period) after EQX – 12.85°; 102.79 minutes after EQX (full period) – 25.70°.

From the last figure, we may draw the correct conclusion that after one full period, the EQX longitude (ascending node) will be located P/4° west from the preceding one (in this example, 102.79/4 = 25.70°).

The effect of the Earth's rotation may be demonstrated another way. Using Fig. 4 with the Earth track (static Earth) drawn on a transparent material and

pivoted on the North Pole, we immobilize the track and rotate the map counterclockwise at a steady rate. The time checks on the track indicate the position of the satellite at so many minutes after EQX. If while rotating the map we mark the location of substatellite points, we will notice that the resulting track will look similar to the one shown in Fig. 5.

For example: To establish the satellite location 10 minutes after EQX, we rotate the map 2.5°; for 20 minutes after EQX, rotate the map 5°; for 30 minutes after EQX, rotate the map 7.5°; etc.

Fortunately, you don't have to go to all this trouble to develop the Earth track for AO-D. For your convenience, Table 1 lists the coordinates for the normalized Earth track for OSCAR AO-D. These equations were used in the preparation of the table:

$$\text{Latitude} = \arc \sin [(\sin i) \sin (360\ T/P)] \tag{1}$$

$$\text{Longitude} = \arc \cos [\cos(360\ T/P) / \cos \emptyset] + \frac{T}{4} \tag{2}$$

where: i = orbit's inclination to equator, P = satellite period, T = time after EQX (ascending node), and $\emptyset$ = latitude (result of equation 1).

Note: Equation 2 minus the last term (T/4) will calculate longitudes for the Earth track on the static Earth. Equation 1 is valid for both the static and rotating Earth.

Employing the above formulas, the Earth track of any satellite in a circular orbit can be easily calculated using a simple scientific calculator, as long as its period and inclination are known.

To use the device, we take published EQX data (time and longitude) of a chosen orbit. Align the zero minute mark of the pivoting transparent ground track on the equatorial longitude of the EQX. Start the clock at ØØ minutes at the time of EQX and follow the satellite's progress minute by minute by relating the time marks on the track to the time indicated on the clock.

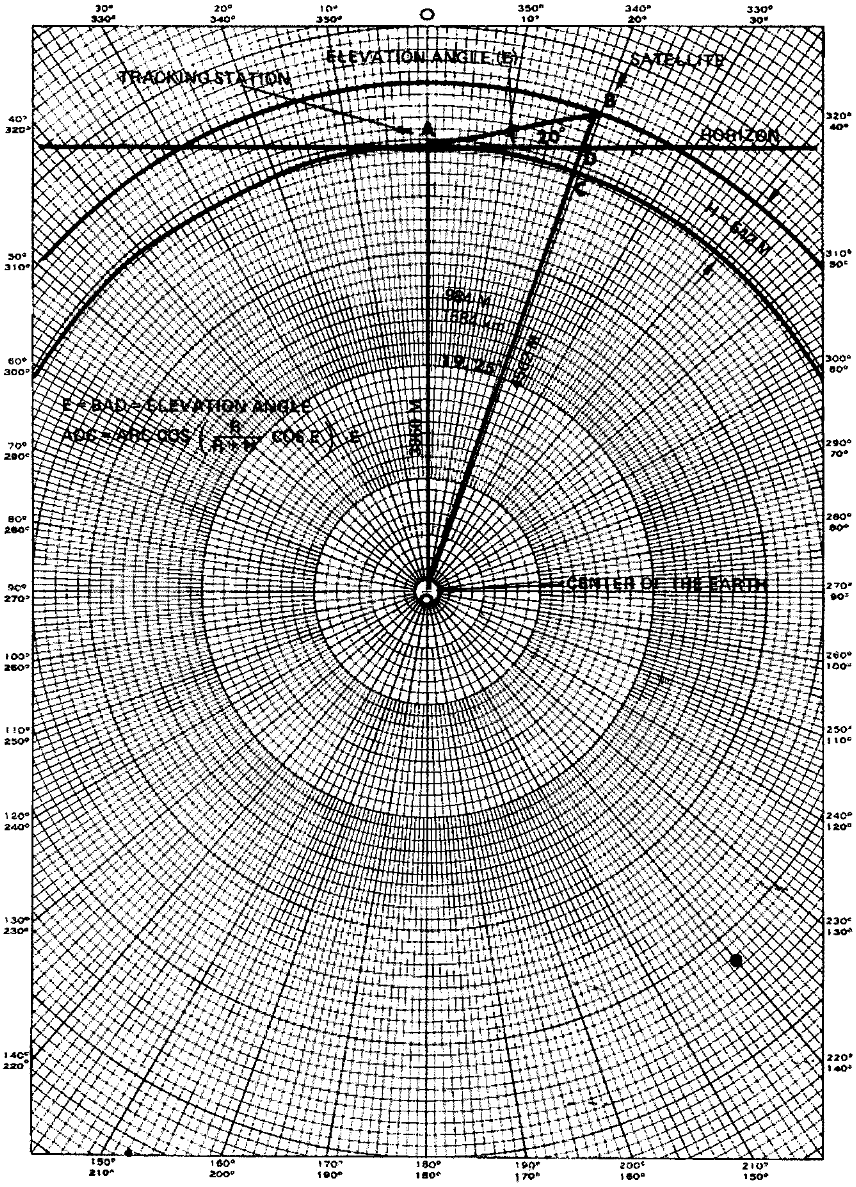

Fig. 10. Calculation of the distance from the tracking station at which the satellite is located 20° above the horizon.

Successive EQX Index Scale

We learned that the longitudes of successive equatorial crossings are separated by P/4° (25.70° for AO-D in which the period is 102.79 min.), and that in order to predict the EQX of the next orbit, we must add that value to the EQX longitude of the previous pass.

This process can be easily "automated" by adding a circular scale to be located under the map and pivoted on the North Pole. The scale consists of index marks separated by P/4° and numbered from 1 to 14. We will consider index mark number 1 as a reference and use it as a starting point for calculations of EQX longitudes of all satellite orbits of one full UTC (GMT) day (see Fig. 6).

Obtaining the data of the reference orbit of a chosen day, we align both the origin of the ground track and the longitude of the reference orbit against index mark #1 on the index scale.

Now, without disturbing the position of the map and the index scale, we can pivot the ground track and set its origin on the successive index marks and read the value of the longitude of the equator on the map. These will be the EQX longitudes of successive passes of the satellite.

In this way, we are able to predict EQX longitudes and follow the satellite's ground track over the Northern Hemisphere throughout the entire day.

EQX Time Scale

We also learned that the

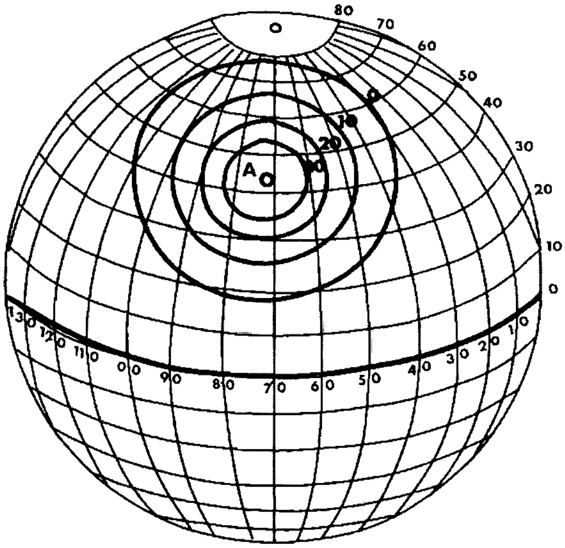

Fig. 11. Circles of equal elevation in respect to tracking station located at A.

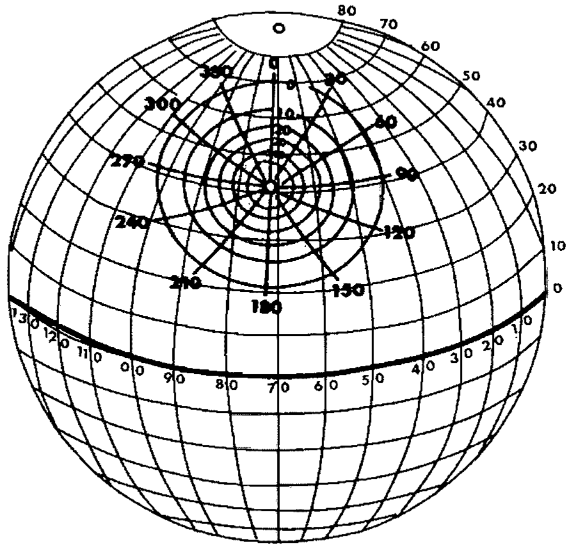

Fig. 12. Complete range overlay showing both azimuth and elevation.

time of the successive EQX can be predicted by adding the value of the period of the satellite to the actual time of the previous EQX. For OSCARs 6 and 7, with periods almost exactly 115 minutes, it was a relatively simple procedure: Two hours were added and then 5 minutes were subtracted. For OSCAR AO-D, with a period of ≈103 minutes, such calculations are a little more cumbersome and prone to frequent mistakes.

In order to simplify this problem, a rotary *time scale* has been added. It is placed between the map and the previously described index scale (see Fig. 7). The circumference of the scale (360°) is divided into 24 sections of 15°, each corresponding to 1 hour of Earth rotation. The hour segments can further be subdivided into 10 minute intervals 2.5° long. If more accuracy is needed, more subdivisions can be made; one minute will correspond to .25° on the scale.

Now, the setting of all scales for the reference orbit is as follows:

– Align the track, the map, and the index mark #1 as described previously.

– Align the exact time of the EQX of the reference orbit also against the index mark #1.

– Now the EQX times of successive orbits can be read directly on the time scale just opposite the corresponding index marks.

Once set for any chosen reference orbit of a particular satellite, both the map and the time scale can be cemented together (but not too permanently) and will not require resetting for a period of several months. The rationale is as follows:

– EQX longitudes are separated P/4° apart.

– During one period of the satellite, the Earth rotates P x .25° (.25° per minute) or also P/4°. Therefore, index marks spaced P/4° apart will correctly indicate the correct time intervals between successive equatorial crossings.

– Cementing the map and the time scale will imply that each longitude of EQX will have a specific time associated with it. This can easily be verified by consulting any long-range orbital predictions. You will find that like equatorial crossing longitudes always occur at the same UTC (GMT) time.

In practice, this relation is not that constant. Due to various factors, such as the solar year not being exactly 365 days, gravitational pull of the moon, etc., a slight drift between both scales will be noticed over a period of time. Therefore, it will be necessary to realign the scale slightly a couple times a year if high accuracy is required.

Summary

An orbital calculator described above consisting of four scales (the Earth track, the map, the time scale, and the index scale) provides a complete satellite tracking system, as long as the data of the reference orbits are available. The system allows prediction of EQX times and the longitudes of all successive orbits of that day. In addition, this system permits tracking the exact position of the satellite during the entire 24 hour period when the spacecraft is passing over the Northern Hemisphere.

Azimuth/Elevation Overlay

Just to be able to track a satellite in respect to the Earth is not sufficient for an OSCAR user. Since the communication via satellite is only possible when the satellite is within the "view" (above the horizon) of the tracking station, the user must be able to predict the rising and setting of the spacecraft at his geographical location. Moreover, if directional antennas are used, the azimuth (bearing) and the elevation (angle above the horizon) of the satellite in reference to the communicating station must be known at all times so the antenna can be aimed directly toward the orbiting transponder.

Communication Range

Fig. 8 depicts, diagramatically, the Earth and the orbit of the satellite. Both are drawn to scale. The Earth radius is 3960 miles (6371 km), and the average altitude (H) of AO-D is 542 miles (872 km). Consequently, the radius of the orbit will be 4502 miles (7243 km).

Point A in Fig. 8 represents the QTH of the user and the horizontal line represents the horizon as viewed from point A. As long as the path of the satellite lies below the horizon, the bulk of the Earth will prevent radio waves from reaching the transponder and no communications will be possible.

At the very moment the satellite crosses the local horizon, it will become "visible" to the user and two-way communication through the spacecraft's transponder will be possible. It stands to rea-

son that at the instant the satellite sets below the horizon, the communication via its transponder will be abruptly terminated.

With the aid of Fig. 8, we can easily calculate the maximum communication range of OSCAR AO-D. Point B on Fig. 8 represents the location of the satellite just crossing the local horizon of a station located at A. A straight line drawn between B and the center of the Earth will intersect the surface of the Earth at point C, which becomes the subsatellite point of the spacecraft just rising above the horizon.

It becomes evident that the distance AC on the surface of the Earth is the maximum distance from which the satellite will be visible from point A. In other words, as long as the subsatellite point of the spacecraft is no further away than distance AC, the satellite will be within communication range of a station at point A.

The distance AD, on the surface of the Earth measured in Great Circle degrees, is the angle AOC. Careful measurements of this angle, or mathematical calculations, will show that for OSCAR AO-D, this distance is 28.4° Great Circle degrees (1 Great Circle degree equals 69.1 statute miles, or 111.2 km).

Therefore, we may conclude that as long as the subsatellite point of AO-D is found within a circle with the radius of 1963 miles (3159 km) from the user's QTH, the satellite will be available for communication.

This circle of accessibility is easily plotted on the globe. Using a compass, measure the distance of 28.4° (using longitude markings on the equator) and inscribe a circle centered on the user's QTH (Fig. 9).

Two stations communicating with each other must have the satellite in view simultaneously. Therefore, their areas of accessibility must overlap. Also, the satellite must be passing through that

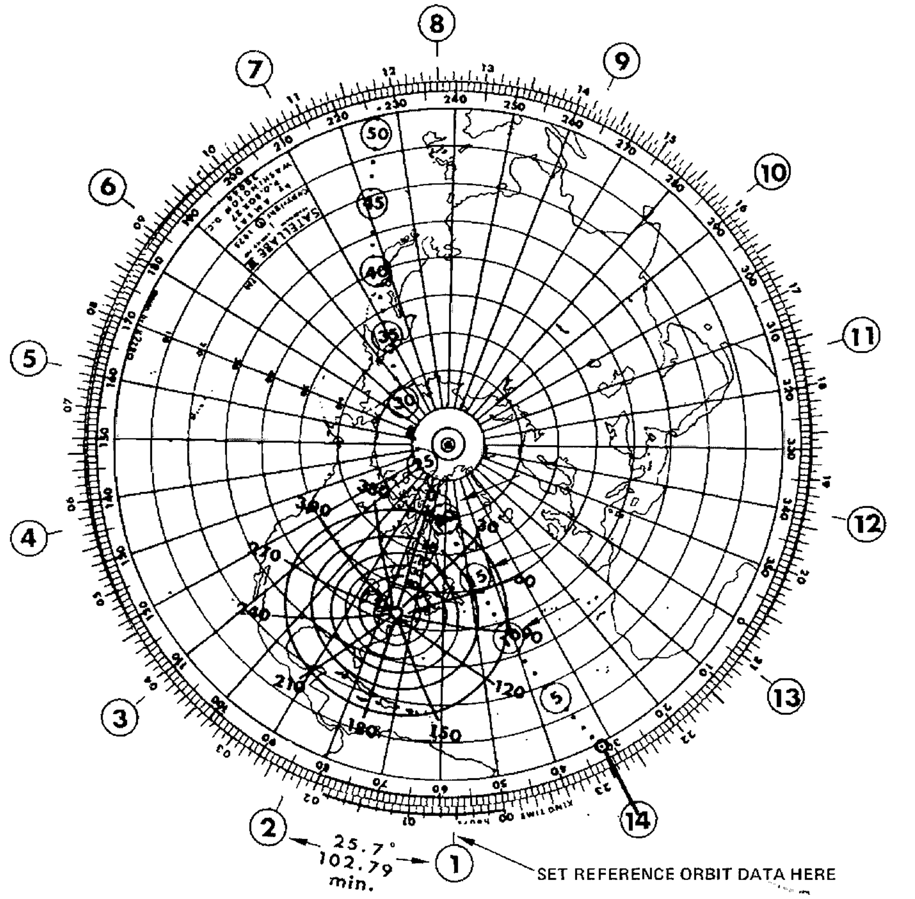

Fig. 13. Complete tracking system. Example: Reference orbit — 0032 GMT, longitude 57.2°. Set these values against index #1. We want to track AO-D during 14th orbit. Under index #14, we read EQX data: time 2247 GMT, longitude 31.8°. Tracking: satellite AOS (acquisition of signal) 10 minutes after EQX, 90° azimuth. 15 minutes after EQX — azimuth 45°, elevation ≈ 8°. LOS (loss of signal) 20 minutes after EQX, 10° azimuth.

overlapping area in order to be visible from both QTHs at the same time. With this in mind, we may conclude that the maximum theoretical separation between two distant stations capable of communicating via AO-D will be 2 x 28.4° = 56.8 Great Circle degrees or 3926 miles (6318 km).

Equal Elevation Range

Using a procedure similar to the one described above, we may plot distances from which the satellite will be seen at a constant elevation angle above the horizon in respect to point A. Fig. 10 shows how it is done.

Angle BAD is the angle of the satellite above the horizon, say 20°. Point C is the subsatellite point at this elevation. Consequently, the angle AOC is its distance from A in Great Circle degrees.

Using a graphical method, or mathematical calculations, distance AD can now be calculated. As in the previous example, a circle corresponding to that distance can be drawn on the globe. Repeating this procedure for different values of elevation angles,

Elev. Angle	c	Distance Miles	Distance Km
0	28.4	1962	3158
1	27.4	1893	3096
2	26.5	1831	2947
3	25.5	1762	2836
5	23.8	1644	2647
10	20.0	1382	2224
15	16.8	1161	1868
20	14.3	988	1590
30	10.4	719	1156
40	7.6	525	845
50	5.6	387	623
60	3.9	269	434
70	2.5	173	278
80	1.2	83	133
90	0	0	0

Table 2. Distance between subsatellite point and tracking station at different elevation angles. Note that even a small topological obstacle that elevates the horizon angle by 3° will shorten the distance of accessibility by 200 miles.

a family of concentric circles can be plotted, each representing a different angle of elevation (Fig. 11).

Elevation angles as a function of distance from the user's QTH for OSCAR AO-D are given in Table 2. You may observe, by examining Table 2, that even a small loss of low angle radiation due to topological configuration of one's QTH may result in substantial loss of the maximum communication range.

Azimuth Lines (Bearing)

Once the circle of accessibility is drawn on the globe, the azimuth, or bearing, lines can easily be added.

If, for example, we want to draw azimuth lines every 15°, we divide the circumference of the circle of accessibility into 24 equal parts and draw straight lines toward the center of the circle as shown in Fig. 12. If azimuth lines at 10° intervals are needed, the circle must be divided into 36 equal parts.

Projecting Azimuth/Elevation Overlay on a Flat Map

Once the azimuth/elevation overlay is drawn on the globe, it can be transferred on the circular orbital calculator described previously.

This is accomplished by transferring coordinates (longitudes and latitudes) of various points of the overlay from the globe to the corresponding coordinates of the flat map. The result will be an elliptical overlay with curved azimuth lines as shown on Fig. 13.

Due to projection distortion, the shape of the overlay will be different for different latitudes of the user's QTH — circular for North Pole and quite elliptical for points close to the equator. It should be noted, however, that the overlays will be identical in shape for QTHs located at identical latitudes.

Notes

1. A globe produced by the National Geographic Society comes equipped with a transparent "cap." If the azimuth/elevation overlay is drawn on the cap, it can easily be centered on any chosen location of the globe allowing instant determination of coordinates for azimuth and elevation points from that location.

2. Those who possess a so-called "azimuthal equidistance projection map" centered on (or very close to) his own geographical location can use it easily for plotting the azimuth and elevation overlay and don't have to resort to the more cumbersome globe. (The ARRL DX map is of this type and is centered on Wichita, Kansas. Other maps centered on principal cities are available from the U.S. Dept. of Commerce, Coast and Geodetic Survey.)

Calculations involved in the development of the az/el overlays are quite complicated and involve knowledge of spherical trigonometry. This subject is beyond the scope of this article.

A circle drawn on the northern projection map (such as used in the ARRL's OSCARLOCATOR) is a reasonable solution, if utmost accuracy is not required. The circle, however, will indicate somewhat shorter than actual range to the west and east of the tracking station.

Application

To use the az/el overlay, we simply follow the satellite's progress and determine its subsatellite points during the pass.

If the location of the satellite is found within the borders of the overlay, the spacecraft is accessible for communication.

Then, the correct antenna bearings are determined by relating the satellite's position in respect to the azimuth/elevation markings on the overlay as shown on Fig. 13. ■

Build A 2m Power Amp

- - great for OSCAR uplink

Class C amplifiers have been popular for some time for 2 meter use. However, to go to the trouble of adding an outboard amplifier, it must produce enough gain to make it worthwhile. A minimum of 6 to 8 dB is required to make the additional amplifier worthwhile and 10 dB gain is desirable.

Many amplifiers I have observed, both commercial and homebuilt, have used two generation old transistors, 2N5590 and 2N5591, for power levels of 10 to 25 Watts. There is a much better device available in the 25 to 30 Watt range, the Motorola MRF238. For comparison of the data sheets of the 2N5591 and MRF238, see Table 1.

At 150 MHz, the gain of the MRF238 is approximately 0.5 dB higher than at 160 MHz (shown in Table 1). The MRF238 is rated at 30 Watts and the 2N5591 is rated at 25 Watts. In practice, the MRF238 has proven much more rugged than the 2N5591 series (more tolerant of high VSWR). The MRF238 also has higher efficiency.

The amplifier shown schematically and pictorially in Figs. 1 and 2 respectively is not unlike many others; however, it makes use of the high performance MRF238.

The performance data in Table 2 was recorded for this

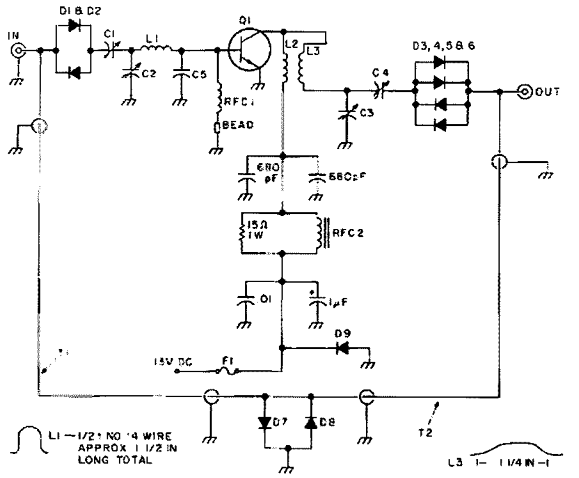

Fig. 1. Amplifier schematic. C1-C4 — Arco 463, 464, or 424; RFC1 — 10t #20 on 270 Ohm 1/2 Watt resistor; C5 -- 3-90 pF silver mica in parallel or 2-150 pF uncased micas also in parallel; RFC2 — 6 to 8 turns #18 around toroid core; L1 — 1/2 turn #14 approx. 1½ inches long; L2 — 4t #14, 1/4" I.D. spaced wire diameter; L3 — Curved wire #14, 1-1/4" long; Q1 — MRF238 Motorola rf power trans.; D1-D8 — 1N4148; T1-T2 — 1/4 wavelength of RG-174 or similar 50 Ohm coax cable; D9 — 2 Amp silicon rectifier.

13.7	2 Watts	26 Watts	11.1 dB
13.7	1.3 Watts	18 Watts	11.4 dB

Table 2. Performance data.

amplifier.

A small loss is involved with the diode switching.

The amplifier was assembled by using single-sided copper epoxy board and cementing small "islands" of board onto the main board. The main board is 2-7/8" x 5" and the minibox is 3" x 5-1/4" x 2-1/8". A heat sink is mounted to the top of the minibox. The only critical items are L1, L3, and C5. Make sure T1 and T2 are an electrical 1/4 wavelength, approximately 13-1/2" with polyethylene coax (RG-174). All capacitors should have leads as short as possible. The amplifier is usable with inputs of less than 1 to 2.5 Watts.

The price of the 30 Watt MRF238 is $8.55 in unit quantities, which is less than the 25 Watt 2N5591 or 2N6082, another point in its favor.

If all items are bought new, the cost is about $23; however, with a reasonable junk box, it can be constructed for about $12 (the MRF238, a minibox, and miscellaneous items not in the junk box). ■

Build A General Purpose Preamp

-- uses common components !

For those of us who are engineers, it is relatively easy to crank out a custom circuit to fit every little need. However, most experimenters and hams are not in that category, and, for them, the next best thing is an accumulation of a few good circuits about which they know a lot. This article describes a simple audio amplifier which has high gain, low noise, and excellent stability toward temperature extremes.

While it is very simple and is used in many commercial devices, it can be used in almost all those places where you need a preamp, such as mike boosters, first af amplifier after a detector stage in a receiver, etc.

Referring to Fig. 1, the circuit can be seen as a direct coupled pair of 2N3904 transistors. This transistor is cheap, high gain, fairly low noise, and very easily obtained. The Q2 transistor is hooked up like any ordinary amplifier stage, but the base resistor that normally goes from its base to ground has been replaced with another transistor, Q1. This Q1 transistor varies the bias on Q2, so the circuit is immune to heat effects. The way it's hooked up, if Q2 draws more current, the voltage on R2 rises, turns on Q1 harder via the 100k resistor connected to its base, and cancels out the increased current in Q2. The result is almost no change in current due to temperature variations. The capacitor C2 prevents the ac signal from being fed back and reducing the overall gain. By placing the capacitor as shown, a very small value, which is also small in physical size and cheaper, will permit the amplifier to keep its full gain to low frequencies as well as would be the case for a very large C placed across R2. The values in Fig. 1 will amplify down to about 10 cycles using a physically small capacitor. To make the amplifier roll off at a higher frequency on the low side, reduce C2 to about 1 uF or less, or, alternately, you could reduce the 100k resistor to about 10k. This would make the frequency roll off around 100 cycles and turn the circuit into a speech amplifier rather than a hi-fi type.

The circuit shown in Fig. 1 performs best when driven by a moderate impedance source from 500 Ohms to 3k Ohms impedance. With this kind of source, the gain will be about 250, and the output noise with no signal in will be about 2 millivolts. This is equivalent to an input noise of only 8 microvolts, so the noise is quite low for all but extraordinary uses.

If you wish to drive the circuit with a low impedance source, such as a speaker of 4 to 16 Ohms or a telephone earphone (which makes an excellent high output mike), use the circuit in Fig. 2. Here, the base is tied to ground via a capacitor, and the signal is fed to the emitter of Q1 through a capacitor. This circuit will perform very similarly to Fig. 1, but will have slightly higher gain reaching perhaps 500 and about the same low noise performance.

Ten microfarad capacitors are used throughout because they are small and cheap, and are more than enough to do the job here.

This simple circuit can be made up in a ball smaller than an acorn and put into mikes to give you more gain than you need to drive even the worst transmitter. It also works well when driven by a speaker put out in the yard to let you listen for prowlers at night, when you don't care to get out of a warm bed, but the dog barks like he's on to something. Fed into any hi-fi input, such a preamp will let you hear better than if you were out in the yard. There are many other uses, and most of them will please you because the low noise of this preamp lets you really hear clean audio. ■

Receive CW With A KIM

-- micro-controlled, of course!

In the January, 1977, issue of *73 Magazine*, WB2DFA presented a fantastic article concerning the use of the KIM-1 microprocessor for the transmission of Morse code. We have used the program repeatedly on the air since that time, and it has been met with never-ending amazement. The KIM was finally given a ham-oriented use. The next step had to be reception of Morse, a formidable project hinged on an entire handful of variables: Morse code was *not* predictable – speeds changed, intra- and inter-character lengths were not constant, word spaces seemed unpredictable, and even sending "style" played a big part. Could it be done? Finally, after much writing, rewriting, hour-long QSOs to solve bugs, and a good deal of hair-pulling, the program worked.

The reader should be cautioned at this point that "perfect" reception is nearly impossible without "perfect" sending. This will rarely be encountered, given noise and the multitude of sounds issuing forth from the CW bands. Suggestions will be offered for copying both hand key and off the air.

The program fits comfortably in the onboard KIM 1K memory. No additional equipment is needed for hand key decoding. Connection to a receiver requires only a simple adapter, which can easily be constructed for under $5.00 with readily available parts. The program allows the option of displaying the decoded Morse on the integral KIM 7-segment LED display or having the output sent to an ASCII TTY or a video terminal. Due to the slow speed of a mechanical printer, only very slow Morse can be decoded. Of course, a high baud rate video terminal will allow the program to run at full speed without getting bogged down in the out-character subroutine. A video terminal usually offers automatic carriage return/line feed at the end of each line. Obviously, these functions are not part of the Morse code and require terminal generation. Using the KIM display allows the decoded material to be displayed in a "Times Square" format, with letters shifting left automatically with the reception of each new letter. The program even offers automatic placement of word space "blanks" between completed words, for easier reading.

Finally, the program here has run equally well on the KIM-1 and also on a 6502-based home brew. It has been tested for several months and, we think, does the best job possible with such an unpredictable code as Morse. Using the program on a KIM is straightforward. Using the program on another 6502-based system would require only changes to call-ups of KIM subroutines and ROM locations. A timer would also be required; the KIM has two built in.

A description of how the program accomplishes its goal is a bit involved. Basically, when pushing "Go," you will see the six digits on the KIM board display random garbage which was in locations 000A-000F when the computer was powered up. About half a second later, the display will shift left one digit, and a blank digit will appear on the right, ready for the first decoded Morse character. After reception has continued for a while, these locations will hold the last six decoded characters. But the microprocessor never sits idle. It is constantly inspecting pin A-8 (PA7) for data input from the hand key or optional receiving adapter. The program loop also checks the onboard timer to see if a 4-millisecond period has elapsed. Each time the timer expires, the loop breaks long enough to increment location 0001. Assuming no code has been received, after about half a second, location 0001 has been incremented up to hex 7F. At this time, the loop breaks again and jumps to the SHIFT LEFT DISPLAY subroutine. Its next move is to the zero page conversion table. The count in location 0007 is used as an offset to select the proper data in the table.

If, as we are assuming, no Morse has actually been received yet, location 0007 will still be at its initialized value, and an error sign will be called up. This data is placed in location 000F, which serves the right-most digit on the KIM board. Then location 0001 is compared to 0005, which was initialized to a value of hex 01. Since 0001

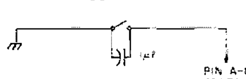

Fig. 1. Connecting a code key to the KIM.

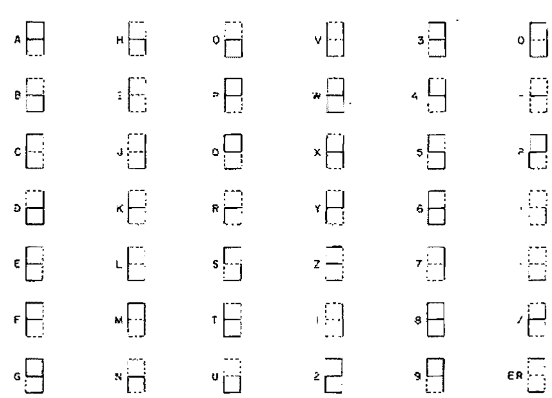

Fig. 2. Decoded Morse code as it will appear on the KIM display.

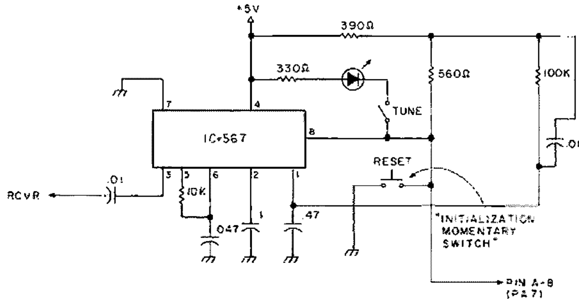

Fig. 3. Tone adapter to use the KIM with a receiver.

will contain a greater count, a second trip through the SHIFT LEFT DISPLAY and the conversion table will be accomplished. This time, the code for turning all display segments "off" will be loaded into 000F. Then the microprocessor reinitializes 0007 and returns to the loop. Also set was 0002, which serves as a flag for the loop to now bypass its checks on the interval timer. Until actual code is received, this final loop will be repeated endlessly. The visible effect on the activity just described is that about one-half second after starting the program, the random data displayed will shift left twice, with the two right-most digits containing an error symbol followed by a blank.

After this has occurred, you will next initialize the code speed. This is done simply by grounding the input pin (A-8), either by holding down the hand key or, if you're using the receiving adapter, by holding down the initialization momentary switch. As soon as the microprocessor discovers that the status of the input pin has changed, the interval timer is put to work again. Holding the key/initialization switch down about one second will allow 0001 to again be incremented up to 7F. Again the loop breaks, but this time a different path is taken because it was learned that the key was indeed "down." Location 0003 is now set equal to location 0001 and will serve as a flag to steer the program through the initialization routine.

Now, as code is entered via the input pin, the program increments location 0001 every 4 milliseconds, to measure the length of time the key is kept down or up. The first key-down is multiplied by two (i.e., shifted left once) and stored in location 0005. Then, it is shifted right two times, which effectively divides the original count by two. This final count gets stored at 0006.

Why get these counts? The microprocessor will use succeeding key-down counts for comparison to those just stored. The processor must decide which was a dot and which was a dash. The first count, by definition, was either less than half the latest count or greater than twice the latest count. If the first count was a dot, initialization is ended. If it was a dash, counts in 0005 and 0006 are updated with the latest count, since proving that the original count was a dash requires that the latest count was of dot length. Initialization, then, requires both dots and dashes so that a comparison can be accomplished. All future counts will be compared to the one now loaded at 0005. Any count less than that in 0005 will be considered a dot; those counts greater will be considered dashes. At this point, all the computer knows is the difference between dots and dashes; we still don't have characters!

So, where does the computer begin to determine that there is intelligence in what it is receiving? The magic begins to occur in location 0007. Every time a dot is received, 0007 is shifted left. Also, for

Table 1. How to use the table: Decide whether you want to have output of the decoded Morse on the KIM's 7-segment display or whether you will be using an external terminal (be it TTY or video). If you want:
7-segment Display — Load the appropriate data in the "7-segment code" column at the specified zero page locations. For example, you will be loading data for an "A" by loading "F7" at location ØØ15. Disregard the "Terminal code" column.
Terminal Display/Printout — Load the appropriate data in the "Terminal code" column at the specified zero page locations. For example, you will be loading data for an "A" by loading "C1" at location ØØ15. Disregard the "7-segment code" column. Note: For terminal use, the KIM-1 requires jumpering of pin 21 to pin V on the Application Connector. Installation of an SPST switch between those points allows switching from the KIM's integral display to a terminal for I/O.

each dot detected, a jump to a speed adjustment subroutine can be taken, if desired (described later). Dashes shift 0007 left once and add "1".

"Key-up" counts must also be considered and serve to complicate the decoding of Morse even more. As long as the counts test to be less than that count in 0005, the program assumes a single Morse character is still in the process of being sent. But as soon as any key-up count exceeds the value in 0005, the single character is considered completed. After a check to see that bit 7 in 0007 is not equal

to a one, the program uses this value as an offset to the zero page conversion table. If bit 7 were a one, the program recognizes that the letter received could not have been Morse (no Morse character is 7 elements long!) and displays the error symbol. Note that, in practical use on the air, errors are followed by a string of dots. The computer will advise you of this occurrence!

We have mentioned the data in 0007 as being all-important, as it represents the actual Morse character. Note several points:

1. 0007 will be initialized to hex 01. (This will serve our "error" condition stated above, if this bit gets shifted left to the 7th bit.)

2. Dots will be entered in this location simply by a shift left (effectively entering a zero).

3. Dashes will be entered as ones.

Morse character "A" will end up in 0007 as "0000 0101" in binary form. The "di-dah" appears in the first two places to the right, with the initial "one" being shifted to the third position from the right. This code for an "A" has a decimal value of "5", and the program at location 025F uses this value, offset by 10, to find the code for an "A" at 0015. At this location, a hex F7 has been entered, if you planned on using the KIM display as your output; if you had decided on using a terminal and wanted ASCII output, a hex C1 would have been loaded instead (see Table 1).

Subroutines are used to shift the display memory, scan that data onto the displays, adjust the code speed during actual operation, and provide for the output of the decoded data to a terminal. Any of these subroutines may be deleted by replacing the appropriate JSR instruction with NOPs. The first two subroutines are required, if the integral KIM display is to be used; the third is optional, to allow automatic code speed adjustment. If you do not use this subroutine, the initial code speed will be considered by the computer to be the only code speed, and it will not adjust to speed changes. Obviously, if you are receiving Morse from a station using a keyboard or another computer, this speed adjustment routine will not be needed and would only serve to complicate matters by slowing the program down. The JSRs to these subroutines are located at:

0243 -- SCANDS – puts the decoded data on the KIM display.

0257 – SHIFT LEFT DISPLAY – allows the data to move "Times Square" format across the KIM display.

02AD – ADJUST SPEED – allows the computer to update the code speed it is receiving.

0263 – OUTCHARACTER – allows the computer to output the decoded character to an ASCII terminal.

For instance, let's say we don't want data to be dis-

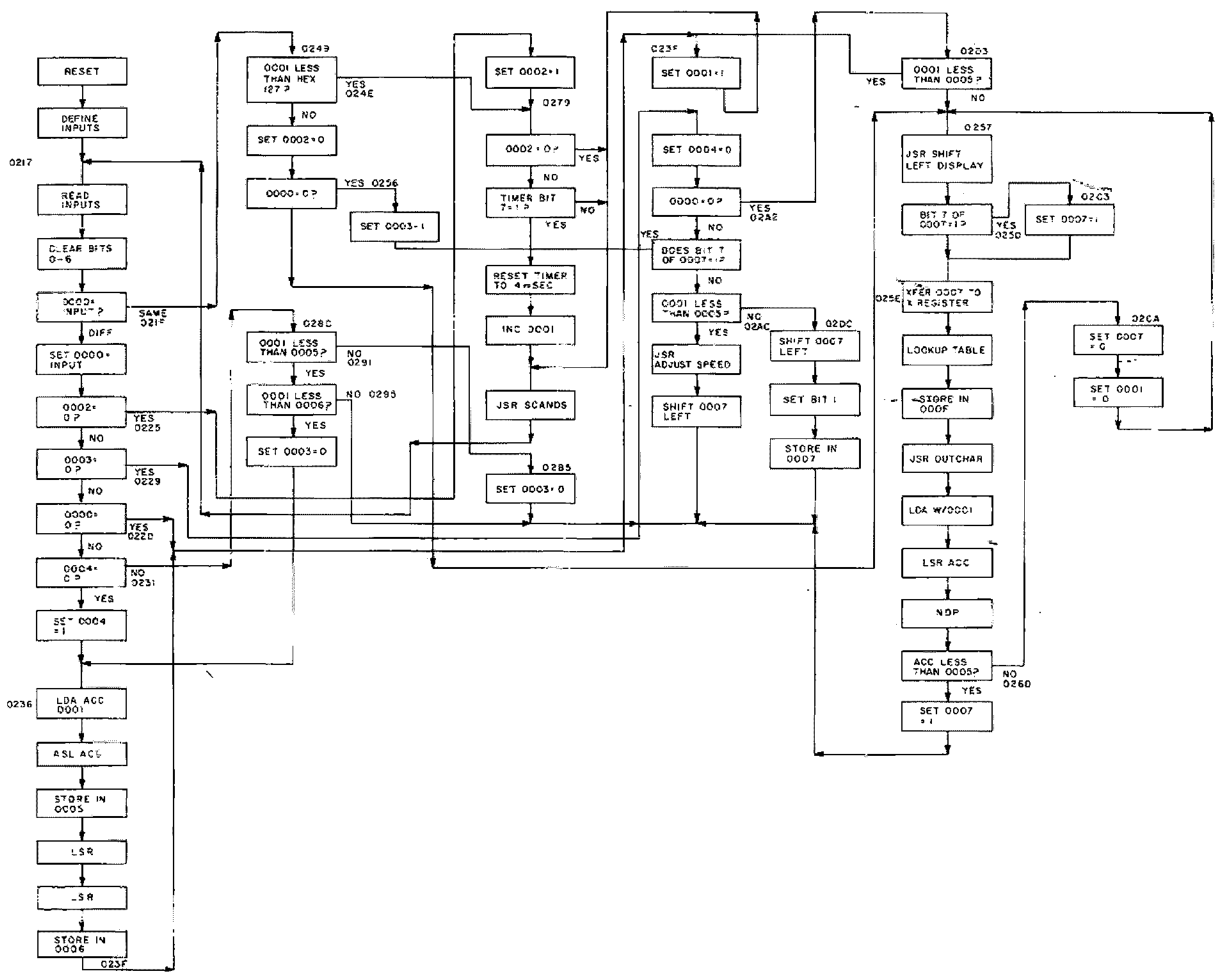

Table 2. This detailed flowchart is intended to give a better idea of operation of the program. Hex addresses are provided at key points.

played on the KIM display, but, instead, we want to use a video terminal. You would delete both the SCANDS and SHIFT LEFT DISPLAY subroutines by removing the JSRs and entering NOPs. Example:

Before
0243 20 0E 03
-
-
-
0257 20 30 03
After
0243 EA EA EA
-
-
-
0257 EA EA EA

Here we have effectively removed the SCANDS and SHIFT LEFT DISPLAY subroutines. Since we have not removed the ADJUST SPEED subroutine or the OUTCHARACTER routine, the resulting program will still adjust to new code speeds and output the decoded data to a terminal. The KIM display will not light. It is pos-

Fig. 4. Program listing. KIM-1 Morse code receive program.

sible to run the entire program unchanged, but running the SCANDS without using it would waste valuable time; running the OUTCHARACTER routine, when you're only interested in the KIM display, could be a disaster. As a good, general rule, remove unwanted subroutines with NOPs. Don't waste the computer's time; it has been given enough to do!

A few words about the heretofore unexplained SPEED ADJUST subroutine – this subroutine, if it has not been replaced by NOPs, will be called up each time a dot is received. The subroutine divides the count stored in 0005 by two and compares the result with the current dot value stored in 0001. Any difference is divided by eight and added to, or subtracted from, the count in 0005. This new value, then, has gradually been adjusted to a new code speed. Obviously, the computer will not accurately handle great single jumps in code speed but does well with substantial changes if they are gradual. Without this subroutine, the initial count in 0005 becomes the dot comparison and cannot change. There is, as usual, one catch to trying to "cover all corners": Occasional bursts of static and noise can easily fool the subroutine into raising the expected code speed. In this case, a string of "Ts" will be displayed. Reinitialization is easy, though. Hold the initialization momentary switch down for about a second. The computer will "start over" in its search for code speed.

Ready to try it? Load the program, the character lookup table (Table 1), and begin by NOPing the OUTCHARACTER subroutine. Connect a hand key to the computer, as in Fig. 1. Although not a major problem, the 0.1 uF capacitor across the key serves to get rid of some switch bounce. Some keys we have used worked fine without it; others seemed to require it. Take a look at Fig. 2, so you have a little idea of what will appear on the KIM display once the program is up and running after several characters.

Since there is no way to display all letters (let alone punctuation!) on a 7-segment LED, we have chosen symbols that seem easiest to identify. Note that an "S" must be distinguished from a "5", an "O" from a "Ø", and even a "T" from a "7". Once you have gotten used to the oddballs, you'll recognize them right away. On a terminal, of course, you'll get standard characters (with the exception of ERROR, which will print as an "@").

If you've gotten this far, set up address 0200, and press "G". Hold the tape key down about a second, then simply begin sending. The first few characters will produce garbage until the computer determines your average dot and dash. Then, you'll see proper Morse being displayed. You'll soon discover how well you're sending. Articulate! The computer and other OM will appreciate it! Try sending the entire alphabet one letter at a time. Pause between each and you'll see a word space placed on the display between your letters. This is an ideal way to get used to the odd characters and to see which letters you don't send very well.

After becoming thoroughly familiar with the program's operation, you will probably want to try it connected to a receiver. The schematic in Fig. 3 offers one suggestion which works amazingly well for its low cost and simplicity. Connect pin 3 of the 567 through the .01 capacitor to your headphone jack. Don't forget to run a ground from the jack to ground on this adapter board. The 567 will be looking for a frequency of about 2100 Hz. This is simply to allow the same adapter to work for RTTY (we're working on it). You won't be able to use a CW filter, since this frequency will be outside its bandpass. When you tune in a CW signal, flip the "tune" switch on. The LED will light when the 567 hears the proper tone. Adjust your receiver from the highest frequency the LED will still light with, to the lowest. Set your receiver in the middle. The circuit is designed to have pin 8 ground when it decodes the proper tone. The 567 will thereby simulate key-up and key-down for the computer. Again, a common ground must be shared between the adapter and the computer. Begin by trying to copy a clean-sending station, one that is on a fairly open frequency, and one that is sending moderate speed (13 wpm is fine). Again, set up address 0200 and hit "G", and then, after a second or so, press the initialization momentary switch down on the adapter board. Let go after a second, and the computer will begin to decode. It is advisable to have the "tune" switch off after you have tuned up.

Should you be troubled by too many word spaces being displayed on slow CW, add a second LSR to the program at 0269. A NOP has been placed there as a space filler. The second LSR instruction lengthens the time that must pass before the computer enters a word space.

In retrospect, a program this simple (anything that fits in less than 1K can't be too involved) cannot be expected to produce perfectly decoded Morse. Your initial patience will be required until you "get the feel" of how the computer is accomplishing this task. The program is not infallible, as it's being required to decode a language overflowing with variables. It does, however, a very respectable job given these conditions. This is at least another step in bringing ham radio and computers together; the future will be what we make it. ■

Build This SSTV Pattern Generator

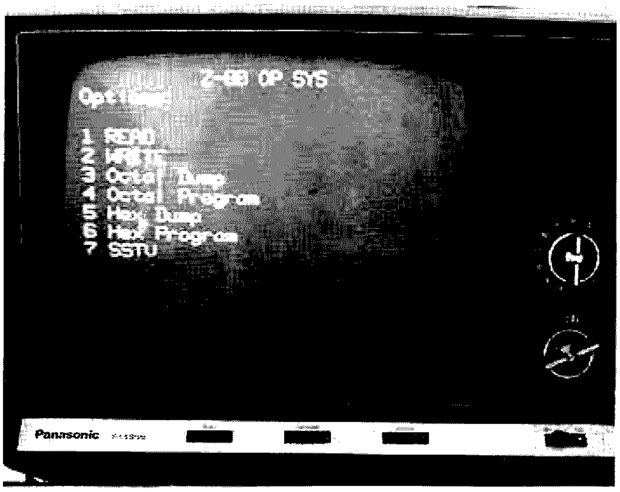
-- now, if only the FCC...

The microcomputer. The large box on the right contains the Digital Group Z-80 system and power supply.

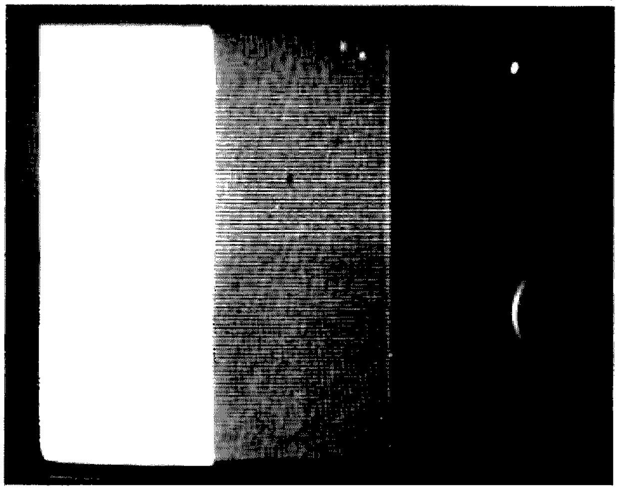
I went directly to programming in BASIC after completing the construction of a Digital Group Z-80 system from a kit. I postponed machine language programming until recently, in order to experience the games and other slow speed applications available in BASIC. I've been interested in slow scan television for the past couple of years, and the generation of a slow scan video signal appeared to be a logical place to get my feet wet in machine language programming. The following program is what resulted. I think you'll find it interesting.

Slow Scan Video Signals

It takes about 7.5 seconds to generate a single frame in the slow scan format currently used by radio amateurs. Each frame begins immediately following a vertical synchronization pulse. This pulse consists of a burst of 1200 Hz oscillations and lasts 30 milliseconds. This is equivalent to 36 cycles, with each cycle lasting 833 microseconds. Each frame consists of 128 lines, and each line starts with a horizontal synchronization pulse which lasts 5 milliseconds. The frequency is 1200 Hz, and the burst, therefore, consists of 6 cycles, lasting 833 microseconds each. Following each horizontal synchronization pulse, there are approximately 60 milliseconds available for the information required to generate one of 128 lines in each frame. The line information consists of oscillations from 1500 Hz to 2300 Hz, with 1500 Hz representing black and 2300 Hz representing white. The line data for an intermediate grey tone only would, therefore, consist of 60 milliseconds of 1900 Hz oscillations, or 114 cycles, each 526 microseconds in length. The fre-



Option list showing the addition of the seventh option.



A 3-bar grey scale.

quency range required to generate a slow scan signal is, therefore, 1100 Hz, between 1200 Hz and 2300 Hz. The generation of these frequencies should be well within the capability of a CPU clocked at 2.5 MHz.

Square Wave Generator

The first requirement is for a machine language subroutine which can generate audio frequency oscillations. Three possibilities were considered:

1. The program would simply generate an 8-bit word, which it would output to one of the available output ports. This word would be used by external hardware in the form of a digital to analog converter and a voltage controlled oscillator, to produce a sine wave of the appropriate frequency. The pro and con are simple software and complex hardware.
2. The program would generate sine waves using only a digital to analog converter at the output port. This would not be a true sine wave, but would consist of discrete steps of voltage changes at the output of the D/A. Each step would require the outputting of a different digital word under software control. Using this approach, the software is relatively complex, and an external D/A is still required.
3. The program would generate audio frequency square waves at the lsb of any output port by simply outputting 01 and 00 alternately. The advantages are simple software, with little or no external hardware required. The disadvantage is that a square wave is generated instead of a sine wave. If sine waves are required, however, low pass filter hardware could easily filter the high frequency component of the output, yielding a sine wave.

The latter was chosen because most SSTV monitors will accept square waves quite successfully. The subroutine, which generates the square wave output, begins at program address 06 78(16) and works as follows.

Prior to calling the subroutine, two numbers are entered into registers H and L. The number which is loaded into register H is a timing constant. It will determine the length of each half cycle and, therefore, the frequency of the generated square wave. The second number, which is entered into register L, is the number of pulses to be generated. The combination of frequency and number of oscillations defines burst duration and function (synchronization pulse or line information data). The square wave generator in the program first outputs 01(16) to output port one. It then loads the timing number, which we previously entered into register H, into the accumulator. The timing number is then sequentially decremented with a check for zero after each reduction by one. On zero, the program jumps to memory location 06 84(16), where a 00(16) is outputted to port one. The lsb of port one, therefore, drops from about (+) 5 volts to 0 volts. The same timing number from register H is then reloaded into the accumulator, and the decrementing procedure begins again. When the contents of the accumulator equal zero, one complete cycle has been generated. The number of cycles number in register L is then decremented by one, and a check is made to see if it is equal to zero. If it's not equal to zero, then another cycle is generated by jumping back to the top of the subroutine. If the number of cycles number is equal to zero, then a jump is made to the return from subroutine statement in memory location 06 99(16).

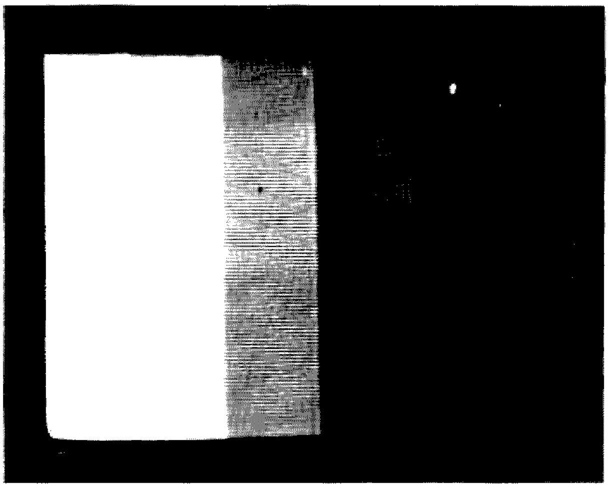
The Timing Constant

Using the square wave generator just described, the numbers which were loaded into register H to determine frequency turned out to be 2B(16) for the 1200 Hz synchronization pulses and 22(16) to 16(16) for the 1500 to 2300 Hz grey shade information. Since 22(16) minus 16(16) equals thirteen, there are 13 different shades of grey which can be generated using this system. One of the patterns generated by this program is a thirteen-bar grey scale.

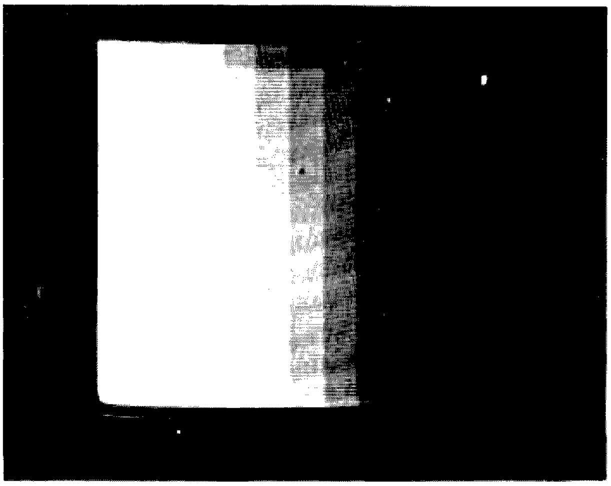
Program Execution

Generally, the generation of the slow scan signal takes place in the following sequence:

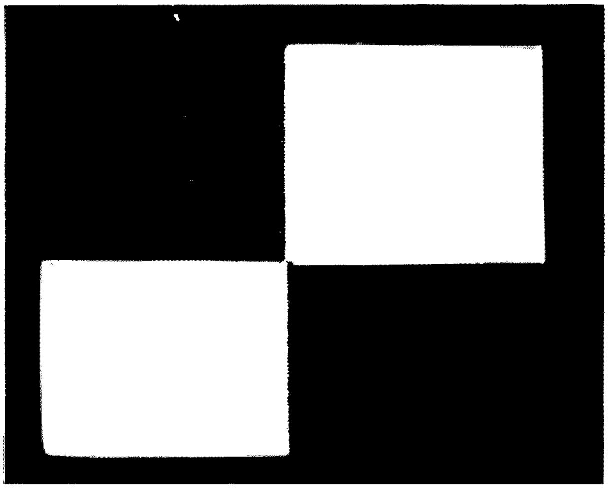
1. First a vertical synchronization pulse is generated by loading 2B(16) into H and 26(16) into L and then calling the square wave oscillator subroutine.
2. Next, the line data subroutine at 06 C6(16) is called. This routine first determines which line data sequence is to be used, then vectors to one of 9 routines. Each routine systematically loads H and L and calls the square wave generator subroutine as many as 13 times to generate the information for a single line.
3. A horizontal synchronization pulse is generated by loading 2B(16) into H and 06(16) into L and calling the square wave oscillator subroutine.
4. The line data subroutine at 06 C6(16) is again called to output line data for line number 2.
5. The sequence of horizontal synchronization pulse



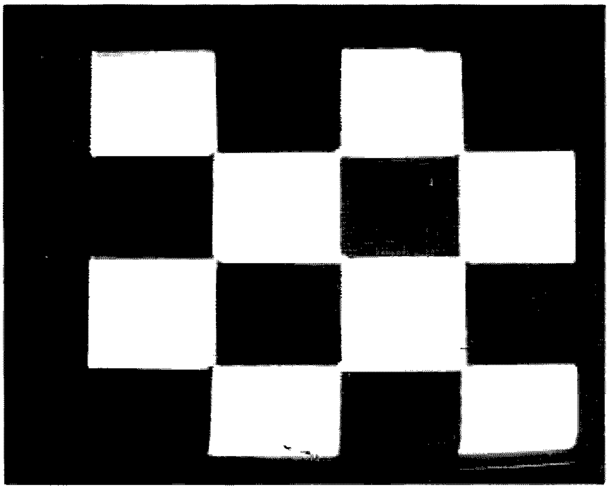
A 5-bar grey scale.



A 13-bar grey scale.



A 2 x 2 alternating checkerboard.



A 4 x 4 checkerboard.

followed by line data is repeated until 128 lines have been generated.

6. The vertical synchronization pulse is repeated after restoring register E to 128 or 80(16), and the next frame begins.

Specifically, I have used the operating system supplied with the computer to implement the program. The operating system consists of cassette read, write and dump and program routines, in both hexadecimal and octal number systems. This is a good place to relate a feature of the Digital Group Operating System which is particularly valuable in debugging machine language programs. By simply inserting an F7(16) into any memory address in the program, you can stop the program and examine the status of all registers in the CPU, and any memory location can be examined or altered. When the system encounters the F7, it stops and displays register status, including all flag status, and it waits for further instructions. I used that feature repeatedly in developing this program, and it's a tremendous debugging tool.

An addition was easily made to the options list, which provided a seventh option of SSTV, as you can see in the photograph. Entering seven results in the message "HOW MANY BARS" being written on the screen. The routine which does this uses a couple of subroutines located in the operating system. As you go through the program listing, any address less than 06 00(16) is in the operating system. If you adapt this program to another system, these subroutines will obviously have to be supplied or the call and function deleted. The remarks in the listing provide function information. The slow scan test pattern generator portions of the program, however, do not utilize the operating system, and, by getting the correct number in address 06 C5 (16), you can select one of nine line data routines. The selections available are:

B1. 4 x 4 checkerboard pattern.
B2. A split screen, with black on the left side, white on the right side.
B3. A 3-bar grey scale.
B4. A 4-bar grey scale.
B5. A 5-bar grey scale.
B6. A 6-bar grey scale.
B7. A 7-bar grey scale.
B8. A 2 x 2 checkerboard, which alternates black and white areas with each frame.
B9. A 13-bar grey scale.

All instructions used in the program are common to both Z-80 and 8080 chips. Instruction execution time may be a minor problem, if the program is implemented on an 8080 system. The number of grey tones which can be generated may be reduced. I have it running on a Z-80 system with a clock frequency of 2.5 MHz.

Results

The output from the lsb port one was connected to

the tape input of a Robot 300 slow to fast scan converter. The patterns were then displayed on a 9-inch black and white fast scan receiver. The scan converter accepted the square waves nicely, and, therefore, no filtering was implemented. The system is capable of resolving the 13 grey tones, when displaying the 13-bar pattern, and the corners of the checkerboard patterns line up quite well. The vertical lines are reasonably straight, and, overall, the generator appears to be doing the job it was intended to do.

Conclusion

Presented is a machine language program which is easily adapted to any Z-80 based microcomputer system. The program generates 9 different slow scan test patterns as square wave oscillations appearing at the lsb of one of the microcomputer's output ports.

Generating these patterns using only hardware would be a monumental task, while producing new patterns with a microcomputer is simply a matter of altering a few software instructions. ■

Super Baud Bumper

-- for your SWTP 6800

I was frustrated by the time that was required to load and punch 110 baud programs on my SWTPC 6800 computer using an ASR 33 as an I/O. So I took a long look at the alternatives offered by SWTPC in the computer documentation. Southwest had apparently settled for a maximum speed of 300 baud, using Kansas City Standard audio cassettes. This would allow loading a basic length program in five minutes, instead of the fifteen minutes required at 110 baud. This would be a significant improvement, but, since you're faced with procurement of additional equipment anyway, why not shoot for something faster?

A careful review of the SWTPC 6800 system revealed that baud rates up to 1200 baud were presently being generated in the system and, in fact, were bused and clearly identified on the mother board and the CPU board. The next step was to settle on an I/O for the higher baud rate, because the ASR 33 couldn't hack it. SWTPC's TV typewriter, with the optional baud rate generator, appeared to be the least expensive route to obtaining an I/O with a 1200 baud capability. Then the only bottleneck in the system appeared to be the serial control interface board (MP-C) in the computer, which doesn't pick up the higher baud rates from the mother board. Alas, why did SWTPC pass up the opportunity to provide the user with full baud rate control (110 to 1200 baud) throughout the system? With the TV terminal, I now had 110, 150, 300, 600, and 1200 baud capability, with the exception of the bottleneck at the serial control interface board.

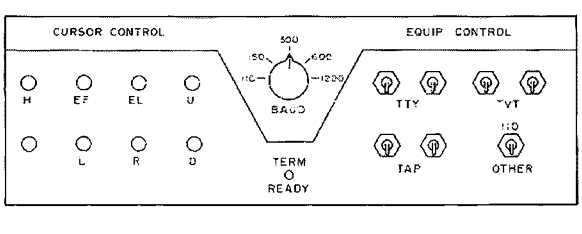

Fig. 1. Panel layout. H = home up cursor to start of page; EL = erase screen to end of line; EF = erase screen from cursor location on; U = move cursor up; D = move cursor down; L = move cursor left; and R = move cursor right.

Investigation of the system design and subsequent discussions with some of the helpful folks at SWTPC indicated that probably nothing would be lost in trying, except the effort. Hoping that all advice was sound and that I wouldn't smoke the system, I began the project. The following paragraphs outline the steps I took and the results I achieved. They are in sufficient detail to guide anyone through the conversion.

Step one was to develop a convenient switching system to permit:

1. Changing of the baud rates, at the computer serial control interface board and at the TV terminal, simultaneously.
2. Interconnecting the tape recorder, the Teletype™, the TV terminal, and the computer; and
3. Control of which pieces of equipment were on line at any given time for maximum flexibility in operations.

To accomplish the modifications at minimum disruption to the up and going system, I decided to provide switches on the control panel already in use at the TV terminal. The control panel already provided cursor control switching for the terminal. A neat little two-pole, five-position rotary switch was procured, which permits separate simultaneous switching of baud rates at the TV terminal and at the serial control interface board on the computer. Fig. 1 shows the panel layout for anyone who would like to cold copy what has proven to be very efficient. The seven momentary contact push-button switches on the left are for the cursor controls.

Space is provided for an additional switch or indicator at the lower left of the panel, if a need should develop later. The two-pole, five-position rotary baud rate selector switch is located in the upper center, with a terminal ready indicator LED located below it. On the right side, six single-pole, single-throw toggle switches provide selective control of the Teletype, the TV terminal, and the tape recorder. Each peripheral is controlled with two single-pole, single-throw switches. This arrangement provides split bus control and permits input and/or output selection of the peripheral units desired. A single-pole, double-throw is shown in the right-hand corner, which controls the baud rate selection at point C on the serial control interface board. Changing point C from low to high controls the number of stop bits at the computer. A subsequent improvement has deleted this control by replacing the two-pole, five-position baud rate selector switch with a three-pole, five-position switch. Wiring of the cursor control push-button switches is described in the TV typewriter documentation and won't be addressed here. Fig. 2(a) shows the wiring diagram for the two-pole, five-position baud rate selector switch and separate single-pole, double-throw switch. Fig. 2(b) shows the three-pole baud rate selector switch, which also automatically switches the baud rate selection at point C on the

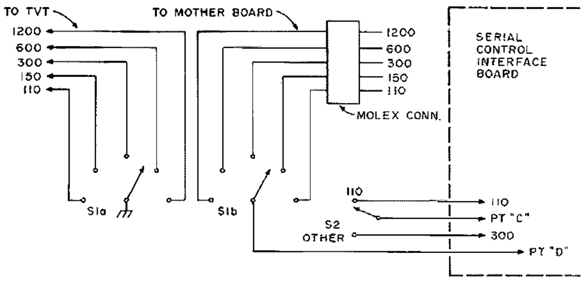

Fig. 2(a).

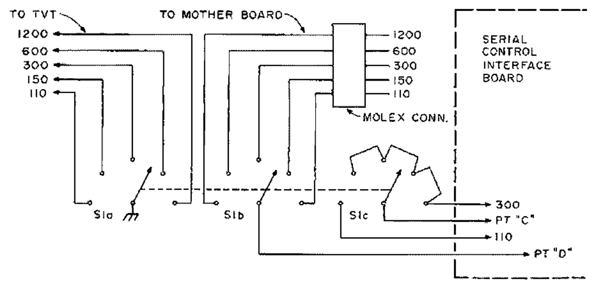

Fig. 2(b). Note that switch S2 is not used in this scheme.

serial control interface board.

The peripheral unit selection switches are straightforward on-off control of the input and output of the RS232 data to and from the units. A wiring diagram for the switching is shown in Fig. 3. Additional peripheral devices can be controlled by additional pairs of switches on the control panel.

The actual connections that were made to the computer and the terminal will be described for those who may be hesitant to experiment. A step by step test out will also be described. The only drawback is the additional wiring that runs from the computer and the terminal to the switches. A neat installation can be had with average care.

Step 1. Locate a convenient place for the control panel. A word of caution: Limit the length of the wires from the baud rate selector switch to the computer to an absolute minimum. You are dealing with digital devices, and long leads leaving printed circuit boards invite problems. I experienced none, but the possibility always exists.

Step 2. Lay out the switching control that best suits your needs. The panel layout in Fig. 1 can be used, if it suits you, or you can come up with your own. There is nothing critical in the layout, only convenience. Mount the switches in the control panel.

Step 3. Solder one set of leads on the baud rate selector switch, S1a. It's suggested that you color code the leads for troubleshooting convenience. Five leads go from switch S1a directly to JS-1 on the serial interface or UART board of the TV typewriter. Connections are shown in Table 1. A sixth lead from the wiper of the switch goes to ground, because grounding activates the baud rate selected by the switch. See Fig. 2(a) or 2(b), depending on which switching arrangement you used.

Step 4. Solder the second set of leads on the second pole of the baud rate selector switch, S1b, using the same color code as used in Step 3. Solder a female molex connector, that matches the pins on the mother board, to the computer end of these leads. This connector can be plugged onto any vacant set of pins from the baud rate buses on the mother board. The molex connector is available from Southwest Technical Products Company, if you can't find it locally. The sixth lead from the wiper of the second pole of the baud rate selector switch, S1b, goes to point "D" on the serial control interface board of the SWTPC 6800. There are no connections to "110" and "300" adjacent to point "D" on the serial control interface board. Be sure to remove any jumpers you may have installed at these points. These two sets of leads should be bundled or six-conductor cable should be used, to provide a neat installation. See Fig. 2(a) or 2(b).

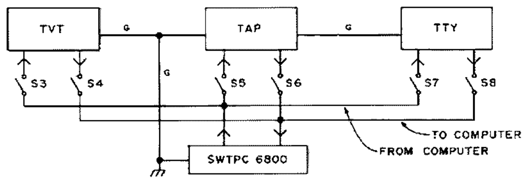

Fig. 3.

Step 5. From switch S2 in Fig. 2(a), connect three wires to the switch. These wires all go from switch S2 on the control panel to the serial control interface board of the computer, so consider bundling them with wires in step 4 for neatness. The center pin of the switch is connected to point "C". The 100 baud speed side of the switch goes to "110" adjacent to point "C", and the "other" side of the switch provides all other baud rates and is connected to "300" adjacent to point "C" of the serial control interface board.

Step 6. Connect the computer side of switches S3, S5 and S7 together. This forms the "output from computer" bus. Connect the computer side of switches S4, S6 and S8 together. This forms the "input to computer" bus. You have now established common input and output buses for the computer. Connect switch S3 to the input side and switch S4 to the output side of the TV terminal (TVT). Connect switches S5 to the input side and S6 to the output side of the tape recorder (TAP). Connect switches S7 to the input side and S8 to the output side of the Teletype (TTY). The grounds for all peripheral devices and the computer are connected together, as shown by line G in Fig. 3.

Step 7. If you want the terminal ready LED, connect the anode of the LED to the terminal ready connection, which is pin 2 of JS-1 on the TV terminal. The cathode of the LED should be grounded through a 250Ω, ¼ Watt resistor. The terminal ready line is limited to sensing and to a 5 mA current, so don't forget the resistor.

Now, if you have carefully checked your connections, you are ready to check out your conversion job. At this point, you probably have abandoned the step by step procedure and have changed things around to suit yourself and that's fine. I did, too, remember! But, for the more timid, I will go ahead with a checkout procedure. These tests assume that you have the optional baud rate generator in your TV terminal and that you have a digital tape recorder (or. have borrowed one). The tests don't have to be performed in any particular order. Depending on the peripherals you have connected, the checkout must be arranged to suit your conditions.

In all cases, the input to computer side of the RS232 connections from the peripherals should show a negative voltage when the peripheral is switched on. Check each one individually at the input to computer bus to assure proper connection. If you don't get a negative volt-

Baud rate	JS-1
110	pin no. 9
150	pin no. 10
300	pin no. 11
600	pin no. 12
1200	pin no. 3

Table 1.

age, try reversing the leads from the peripheral you are testing.

Test 1. Open switches S3, S4, S5 and S6. Close switches S7 and S8. Set baud selector switch to 110 baud. Set switch S2 to "110". This arrangement connects only the Teletype to the computer. Test your Mikbug™ memory address functions — they should work normally. If they don't, you have probably reversed the leads from the Teletype to S7 and S8, so try reversing them. If you are satisfied at this point, load a machine language program such as tic-tac-toe or blackjack into the computer via the paper tape reader on the Teletype. Open switches S5, S6, S7 and S8. Close switches S3 and S4. Set switch S2 to "OTHER." Set baud selector to 1200 baud. Type in "S9" and "G" on the TV terminal, and the program should be initiated at 1200 baud. Check the remaining baud rates, 600 to 150, on the TV terminal. Change S2 to "110", and check the 110 baud rate out. If this step has checked out, go to test 2. About the only problem you would encounter is reversal of leads from switches S5 and S6 to the tape recorder.

Test 2. Open switches S5, S7 and S8. Close switches S3, S4 and S6. Set baud rate selector switch to 1200 baud. Set switch S2 to "OTHER." This arrangement connects the "from computer" side of the tape recorder and the TV terminal to the computer, and it sets up for a print-punch operation, which will transfer the program resident in the computer to the tape recorder. After you have the program dumped to tape, turn the computer off to clear the program from memory. Power the computer back up. Using the TV terminal at 1200 baud, type "L" to initiate the program load function. Open switches S3, S4, S5, S7 and S8. Close switch S6. Load the program from tape into the computer. Open switches S5, S6, S7 and S8. Close switches S3 and S4. Initiate the program at 1200 baud by typing "S9" and "G". Go through the above listed procedures for baud rates of 150 through 600. Then set S1 and S2 to "110", and check out the 110 baud rate for dumping and loading of programs.

Test 3. If steps 1 and 2 were successful, let's proceed. So far we have checked out the Teletype, the TV terminal, and the tape recorder, individually. Now it's time to try split bus operation. Set the baud rate selector switch and switch S2 to 110 baud.

Open switches S4, S5 and S6. Close switches S3, S7 and S8. We now should be able to input data from the Teletype keyboard and output data on the Teletype and TV terminal, simultaneously. Try it and see. This will only work at 110 baud, because that's the limiting speed of the Teletype. Experiment with the other functions.

There are obviously other tests you could run, but, if tests 1 through 3 were okay, you should now have a system that has reduced load and print-punch time by a factor of 12, if you were using 110 baud, and by a factor of 4, if you were using 300 baud. Quite an improvement, wouldn't you say? We set out to provide faster loading of the SWTPC 6800, and we succeeded!

Once again, if you are reasonably careful you probably will have no problems. Too long leads from the baud rate switch to the computer could cause problems, but check for wiring errors, switch setup errors, and/or reversed wiring before you blame lead length. I hope this gives others as much fun as it's given us. I would like to see what control panel and switching arrangements you come up with, so how about dropping me a line and sending me a picture? ■

QRZ -- P-K4!

-- relax with ham chess

Russell C. Parker W9CQD
7814 Keeler
Skokie IL 60076

Avid chess players will recognize P-K4 as the opening Bobby Fischer uses in the majority of his chess games. What's your favorite, and have you tried it on ham radio? There is plenty of radio chess going on in the ham bands. If you like chess, why not join in? You don't have to be an expert, you just have to like the game. Combining two interests makes them even more enjoyable.

OK, you say, I like chess. Where can I find a game on the radio? First of all, here are some frequencies where chess players can be found: Midcars, 7258 kHz; Eastcars, 7255 kHz; and Westcars, 7255 kHz are service groups which operate most of the daylight hours. Check in and ask if any chess players are on the frequency. When you make contact arrange to QSY and start your game. If you don't make contact ask the service control to list your request or just monitor for a while until someone else checks in and asks for a chess game.

Another frequency to monitor, starting about noon, is 7235 kHz. There is a pretty regular group on every day, and they will welcome some fresh talent. Evenings, after 7 pm, try around 3990 kHz and 3928 kHz for two other informal, friendly gatherings.

Now for some tips on beating the dipoles for opponents on your own. Firstly, bring up the subject during your usual QSOs. It's surprising how many hams you will find who know how to play and might be interested in a game. If they don't have time immediately, try to arrange a schedule. Check in any traffic net, and make a request for chess players. Always move off frequency quickly. Decide beforehand where you want to move so you will not hold up the net. Contact any local amateur radio club. Leave your phone number with the officers, and ask them to inquire of their membership whether anyone would like to set up a schedule. Put out a call on 2 meter FM repeaters. Again, always arrange to QSY quickly when you make contact with a player. Ask your opponents if they know of anyone else interested in playing radio chess. Keep at it, and soon you'll have a good list to choose from.

Now for some hints about actual play. It may be a little hard to maintain concentration because of noise or QRM. Remember, this is for fun, so enjoy it and don't fret about losing a game or two. You'll find a great variety of skill in the various challengers, so if you are up against an excellent player, don't prolong a game when you are down one or more pieces. Resign and start over rather than try to make him mate you. He's more apt to be willing to play you again.

Always score the game, that is, write down the moves. This helps if you have a mix-up and want to straighten out the board. Say

Rus W9CQD playing radio chess.

your moves twice and always acknowledge the other fellow's moves. In radio chess you have the opportunity to move the pieces around to see how a particular position looks, and it is easy to forget to move a piece back to the right square. Try to avoid this if you can. You certainly would not be allowed to do it if you were playing across the board. It becomes a bad habit as well as leading to messing up the board.

Don't be afraid to play because you don't know chess notation. It can be learned in a few minutes. Ask an experienced player to explain it or check any elementary chess book at your local library. Try not to talk to your opponent while he is contemplating his move. Sometimes it helps to keep the frequency clear if two or three games are going on at the same time. It may be a little hectic at the beginning, but after the moves start slowing down, you'll be able to maintain the frequency since someone will be making a move more frequently than if only two were playing, and it won't seem like the frequency is clear. Explain to polite hams who ask if the frequency is in use that you are playing chess and are quiet between moves.

Don't rule out CW for your games. They can be just as rewarding as phone. Also, look out for the ladies. They play, too, and some are excellent players.

When you get established, why not go for PAS – Played All States? DX hounds will find overseas players, though the bands may not hold up for the length of the game. You may want to adjourn a lengthy game and finish another day, another reason to write down the moves. No reason not to try SSTV or RTTY either.

And who knows? When you get a winning streak going, try for a phone patch to Bobby Fischer. ■

Digital Timer Goes Mobile

- - battery power keeps it trucking !

Frank W. Knottingham K7QCM
P.O. Box 734
Gold Beach OR 97444

Having built the frequency counter written up by Thomas Harper and published in the August '73 issue of *73 Magazine*, three alarm clocks from the 50250 chip outward and five of the 5314 kits, I was captivated by the flying numbers, and it was easy to convince myself that I needed a time period counter in my service truck.

So I built up out of 7400 series ICs a 3 digit timer to count the time I was on a service call. This worked quite well until the engine of the truck was started during the counting period. Then the readouts would maybe show correct time interval or maybe not. So back to the old think tank and, lo, the perfect interval counter was born.

An order was sent off to S.D. Sales for their current clock kit using a 50250 chip and a 60 Hz CMOS timebase, which was the one being advertised at the time. The two kits were assembled and mounted in a small 10¼ cm wide by 4 cm high by 11 cm long metal box hinged to a base at the lower rear corners. Two switches were installed in the bottom of the box. A push-button switch as used in a table lamp turned the 12 volts from the car battery on and off at a touch of the top of the metal box. At the same time a microswitch made up of two miniature micros fastened together and operated by a common push-button served to momentarily connect the hours-set and minute-set pins of the clock chip to the positive supply voltage which then would start the seconds counting. This interval timer has been in use for a couple months now and has not been caught giving a false reading.

When power is interrupted, a 50250 clock chip will return to either 12:00:00 or all zeros, depending on whether it is used as 12 hour time with a 60 Hz timebase or 24 hour time with a 50 Hz timebase. Some day I will get a CMOS 50 Hz timebase and go for the 24 hour format. At the present, starting at 12:00:00 is a bit awkward, especially around noon time.

Why didn't the original timer work? My best guess is that since the 7400 series ICs needed 5 volts, which were obtained through a 309 regulator IC which requires at least 10 volts for stable regulation, then probably the starter pulled the voltage down to or near this point and caused the confusion.

The clock chip and timebase use 12 volt supply direct and are quite tolerant of low voltage.

A cabinet to house a project such as this always presents as much problem as the circuitry, to me at least. What really took place there was that during the first lash-up and test period I found a box made of thin cardboard that just fit the circuit boards. The timebase was wrapped in crumpled newspaper and shoved down in this cardboard box. Then came the main circuit board with the clock chip on it, and the readout board was last with

Photo by Wally Blackburn K7SEG

the readout board plugging the whole box top and the switches dangling. This lash-up was tied to the steering post and put through the smoke test in this unfinished condition. When it looked like everything would work, a metal box was made to just cover the cardboard box; a hole drilled through this received the push-push power switch, which in turn held the works in the metal box. Another hole permitted the power wires to be led out and the two microswitches to be wired outside of the box.

The choice of switches is a determining factor in the placement of the microswitches and the lever arrangement. In this case the two microswitches were lightly hinged to the box by putting small screws in the plate of the switch pair and the push-buttons of the switches up against the box. The wires are stiff enough to provide the necessary force to close the switches. If the larger microswitches requiring more force to trip them were used, it would be necessary to provide a spring to supply this force, as a push-push switch needs an overrun on the stroke to trip it. The hours and minutes switch can be closed first, but has to give down enough for the push-push switch to turn the power on.

The current available 50250 clock chip seems to have turned into a 50252, possibly an updated version. There may be other clock chips which will work, but remember the requirement: The readouts must go to zero when the power switch is opened and closed again. Many of the clock chips will show some random number which, of course, is unsatisfactory.

A one finger push down toward the base will start this timer counting the seconds, and another push will turn the whole thing off again. ■

Straining the Wind

- - simple wind speed indicator

This article describes a simple wind speed indicator which can be built very inexpensively and is complete within itself. It can be constructed as just a fun project or can have a serious application in functioning as an alarm indicator to indicate that a certain wind speed is being exceeded and a beam should be lowered. For those who desire to build a more precise anemometer, refer to the article "Inherit the Wind," *73* for March, 1976. It describes a very good home brew wind speed indicator. Its advantages are accuracy and the detection of low wind speeds. It requires a bit of circuitry, a power supply and a frequency counter as an indicator. The wind speed article described in this article is far from that elaborate, however; it requires no power supply, is a self-contained unit, and can serve the basic purpose of "saving your beam."

The heart of any wind speed indicator is a device that will generate and/or transmit a voltage proportional to the speed at which the wind vanes are rotating. Quite by accident, it was discovered that the dc motors found in cassette tape players make excellent little dc voltage generators when their shaft is externally rotated. These motors are inexpensive but relatively well-made as a mass-produced item. Their bearings are good enough that they should last for several years of service and of low enough friction that a moderate size wind vane will start the shaft turning in anything more than a gentle breeze. They can be purchased from various surplus outlets for a few dollars, or almost any serviceman will have a few available from discarded cassette tape players. Don't confuse this type of motor, however, with the "cheapie" dc motors used in toys. The latter type of motor will work also as a dc voltage generator, but will last only a short while in continuous rotational service.

The motor-turned-generator can be secured to a mast with a large hose clamp, or a much neater mast mounting arrangement can be made using a bell-type reducing joint. The latter can be found in plumbing supply houses. They are meant to join pipes with fairly great thread diameter changes. Usually one can be found which will mate with a desired mast diameter, and the large end of the bell joint then forms a cup into which the dc generator can be snugly fitted and glued into place.

The construction of the wind vanes can be as simple or as elaborate as one desires. The overall dimensions shown in Fig. 1 yielded good results with winds ranging from a bit more than a light breeze to gale force winds. The principal requirement is that the vanes turn in one direction only or else the generator will not always produce a voltage of the same polarity. To ensure this, some sort of cup or cone assembly is needed at the end of each vane. The assembly shown in Fig. 1 is about as simple as one can get. The center piece of the vane assembly is a plastic cover from a large glass jar. It serves two purposes. One is to act as a central mounting piece for the vanes, and it also serves, because of its shape, as a weather cover for the upper part of the generator. The generator used had a pulley permanently attached to the shaft, and apparently most all cassette motors come this way. The end of the pulley was filed flat and then the jar cover fastened to it with epoxy cement. The individual vanes are simply plastic sauce strainers found in a household goods store. The strainer holes are sealed up by painting them, and the handle end is secured to the jar cover by some screws. The whole assembly does look a bit funny, to say the least, but it works. It can be made a bit more professional-looking by a good overall aluminum spray painting. Also, once it is up in the air, the simple components of its construction are no longer as obvious.

The generator voltage is transferred by regular line cord to a remote indicator. The remote indicator can be a simple meter or something more elaborate, like a digital readout. The generator will turn fast enough to easily activate a microampere meter even over long transfer line lengths. In very high winds, enough voltage will be generated to activate an LED. Fig. 2 shows a remote indicator circuit using a 150 uA meter. An adjustment potentiometer allows the meter to be set for full scale with a strong wind blowing. The optoisolator circuit (an LED and a switching transistor in an IC package) can be used to switch on a buzzer or bell when a particularly high wind gust is sensed. The main value of this feature is that one can be alerted, usually during the night, of the presence of a high wind condition. The meter can be approximately calibrated in wind speed values by comparing its reading to locally broadcast weather reports under various wind conditions. ■

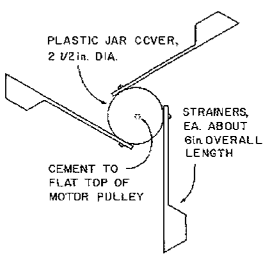

Fig. 1. Advanced design wind vane assembly.

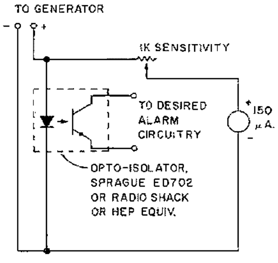

Fig. 2. Remote indicator. Alarm circuitry might be a 6 volt battery in series with a Mallory Sonalert, for example.

Find That Meter Resistance

-- with this simple bridge

There comes a time in every ham's life when he must seek that unknown meter resistance. Here's a simple solution to that age-old problem. The schematic is shown in Fig. 1. It's equivalent circuit is shown in Figs. 2(a) and 2(b).

In Fig. 2(b), R2 is equal to R2, and R_{BP} is the equivalent parallel resistance of branch 1 and branch 2. Neglecting R_{BP}, the current through R2 would be 1.5 (E)/ 1500 (R) = .001 A or 1 mA, the full-scale reading of most meters. Thus, when we reinsert R_{BP}, we know that the current is less than 1 mA. This keeps the current through each branch (Fig. 1) less than 1 mA, protecting both meters.

In Figs. 1 and 2(a), when the resistance of branch one is equal to the resistance of branch two, the currents through both are equal. Thus, you know that when the reading on the meter under test and the current reading on your meter are equal, the resistances of the two branches are equal.

The resistance of branch one is equal to the resistance of M1 (which *must* be known) plus R1, a potentiometer with a calibrated dial. If we select Rx so that it is equal to R_{M1}, then, when R1 is equal to $R_{M\text{-test}}$, the resistances of the branches are equal. If the resistances of each branch are equal, the currents through them are equal.

To find the meter resistance, one must plug in the meter under test and rotate R1 until the currents through both meters are equal. Then we know that R1 = $R_{M\text{-test}}$ and its resistance can be read directly off the calibrated dial.

The smaller the value of potentiometer R1, the more accurate is the measurement of $R_{M\text{-test}}$. This is because the dial can be calibrated in smaller units.

As an option, a more accurate circuit is shown in Fig. 3. A rotary switch can select different values of resistance to be added to R1. Thus, R1 can be made as small as you wish. $R_{M\text{-test}}$ is now equal to R1 plus the switched-in resistance.

Let's say you wanted to measure a meter's resistance using only R1 (Fig. 1). If your dial was calibrated with 100 notches, the result would be 5 Ohms per notch. If we use the circuit in Fig. 3, the potentiometer is only 200 Ohms, leaving 2 Ohms per notch on the same calibrated dial. Thus, we see how there is more accuracy in a circuit such as the one shown in Fig. 3.

I would suggest that you choose a meter with a low resistance. Also, if you prefer, you can use an ohmmeter to read the resistance of R1, thus saving yourself the trouble of finding a calibrated dial.

As you can see, the circuit is a flexible one and can be customized by the builder. All that is needed is a pen, paper and E = IR. ■

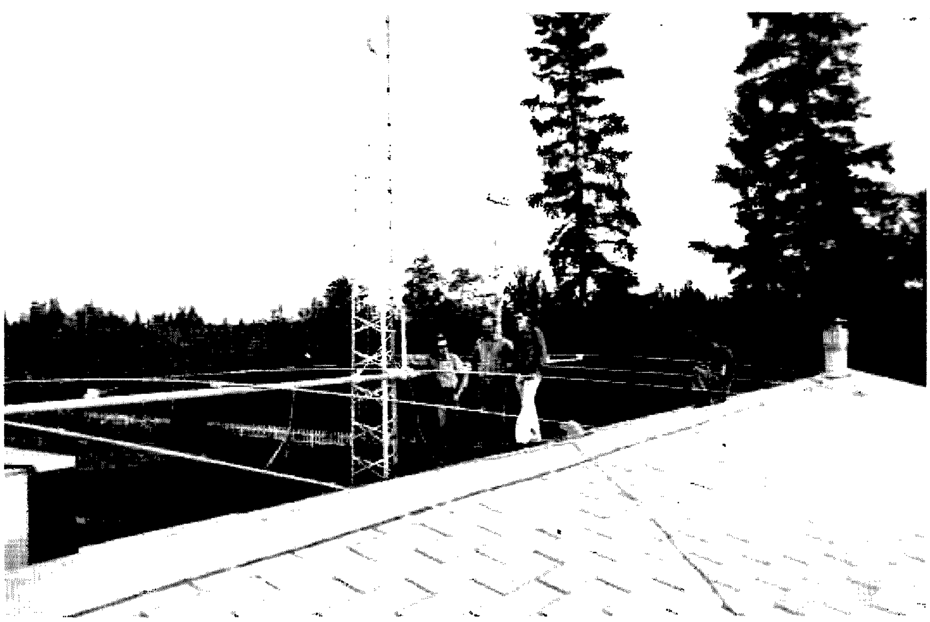
VE6 DXer Tells All!

-- what to do all winter

During the fall of 1971, I took the opportunity to transfer from VE6 land to VE8 land to work in what was at that time the largest national park in the world, a total of 17,300 square miles of wilderness.

Wood Buffalo National Park straddles the boundary between the Province of Alberta and the Northwest Territories. The park holds the distinction of having the largest herd of free-roaming bison in the world and the nesting site of the endangered whooping crane.

We arrived in the small community of Fort Smith, N.W.T., with an approximate population of 2,500, on January 12, 1972; it was -40° C. After traveling for 1400 miles on winter roads with a house cat and a back seat full of house plants which were still alive, it was a godsend to be at our new home. It was a land not very well known by the average North American, let alone the average radio ham.



From left to right: VE8NS, VE8LG and VE8RZ.

The area is located in the northwest extremity of the Great Northern Plains, well within the Boreal Forest Region. It is a land of sharp contrasts, 24-hour daylight, a semiarid region with 10-12 inches of precipitation per year, and hordes of mosquitoes and black flies that could drive a human being crazy in hours. It's a land of northern lights, -50° C., dog teams, hunting and trapping still a way of life, short winter days, and ice crystals to brighten the way.

At the time of my arrival, Terry Keime VE8OK was an avid DXer. I enjoyed the bands from this QTH. VE8s were in demand, which made DXing interesting. With the eventual arrival of VE8OO and VE8RO on the same block, would you believe we had QRM alley in VE8 land? There it was in full bloom. I checked out the ham population, and, according to the list, there were 82 licensed operators, with approximately 20 active hams. And three of them were on the same block.

Time was the pacifier until the opportunity presented itself – a move to the other side of town. Now was my chance to get away from rf burns on everything I touched.

Once we were settled in, with beds on the floor and boxes piled everywhere, my thoughts turned towards an antenna structure. The days were becoming shorter and colder rapidly. The concrete base was poured by candlelight, and prayers were said for a warm weekend, just one good weekend to put up the structure. God was willing, and the antenna was on top with hours to spare. The following week proved how unpredictable the weather can be – snow and wind with minus 10° C. (It's a smug feeling to have all the outside work done.) The antenna performed as expected,

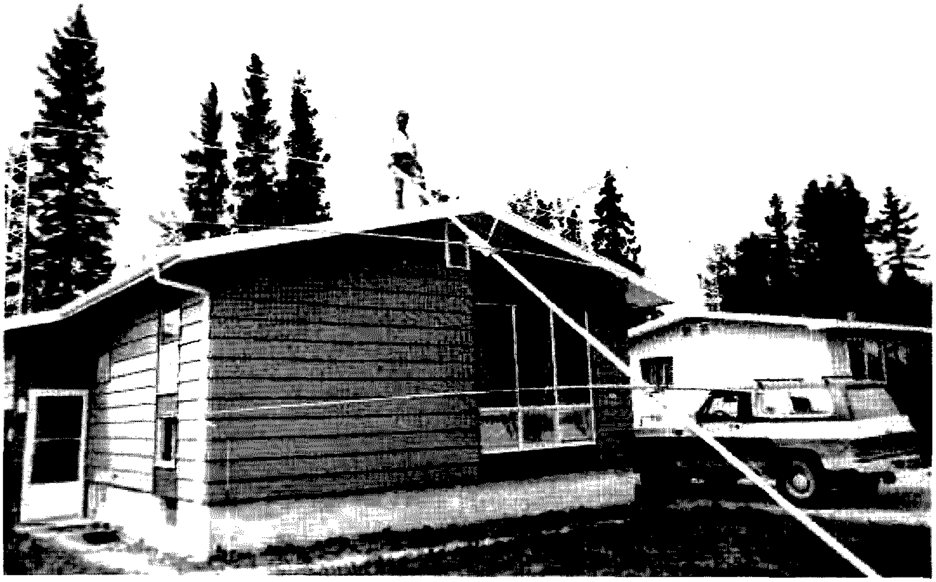
loaded well, and all that was left was to pile up the DX.

But my rule of the roost was soon to be shattered with the arrival of an old friend, Gerry VE8LG, a graduate from an electronics school and now a radio inspector with the Department of Communications in Fort Smith, N.W.T. The die was cast. Gerry was moving in next door! How is this possible with 2 million square miles of VE8 land? Two DXers squeezed into an area of 1,000 square feet made me wonder at the mathematical odds and shake my head.

Once the initial shock was over and I became somewhat rational, we discussed old times, invariably getting around to amateur radio. A plot was formed. VE8LG had intentions of purchasing a Wilson 520 (for the uninitiated, the Wilson 420 has 4 elements on a 30' boom; the 520 has 5 elements on a 40' boom) and a self-supporting 64' tower to support the beam (with a Ham II rotator to turn it). The entire construction procedure went well and 5 elements were soon up.

The area of residence of VE8NS and VE8LG was taking on an air of space age mystery. In the space of 100', two 64' towers and one 40' tower, supporting a Wilson 520, 420, and 415, and an inverted vee for 40 and 80, were serving two amateur radio stations – the VE8LG Kenwood twins and the VE8NS TR-3 Drake line. We were rather amused whenever people or vehicles passed by. Invariably they slowed down to look at all the flying aluminum and shake their heads, with quizzical looks as if to say, "What is going on here?" Thank goodness for rather nonstringent town bylaws, or we would not have been allowed to proceed.

Tests were started immediately, and, as expected, the beam performed according to specifications. We decided to hook both transmission lines to an antenna switch. Since VE8NS' beam was only 50' away, it presented no problem to extend a coax a little bit.



VE8NS contemplating the job.

The results from the experiment were confusing. With both beams pointing to Europe, transmitted signal strengths were basically the same in all cases. However, on received signals the 520 beam registered as much as 3 S-units over the 420 beam. In some cases we were unable to copy signals on the 420 beam which were an S2 on the 520 beam.

With beams pointing toward ZL-VK land, again we were in for a surprise. ZLs were consistently giving better reports from the 420 beam than from the 520 beam, by as much as 1 S-unit. At no time were the transmitted signals better on the 520 beam. Received signals were better by as much as 3 S-units on the 520 beam. Perhaps further experiments will be carried out to determine whether adjustments to both beams may change the present pattern. However, the experiments were a lot of fun. Maybe the old adage, "the bigger the better," does not hold true in this case.

It is impossible to work on the same band. However, with 15m openings, VE8NS is able to operate with minimum QRM. If all the bands are out, then work is continued on the 2 accu-keyers, with one working and one more to go. But that's another story.

A matter of interest to hams looking for contacts in zone 1 VE8 land – VE8RZ, VE8LG, VE8OV and VE8NS are active on 20, both CW and SSB. VE8NS is the QSL bureau manager for VE8 land.

A thought just occurred to me, I haven't noticed any rf burns at this QTH. Could it be there never were any? ■

meter), and a laminated vswr chart. The price for this equipment is $298.

The test set is cushion-fit assembled in a durable, MIL-spec polyethylene case with space for seven plug-in elements, which determine power and frequency ranges. The carrying case and vswr chart are complimentary with the kit.

A customized luggage-style transit case has also been announced. Model 4300-070 has space for a Model 43 wattmeter, 15 plug-in elements, and additional accessories. Cushion inserts for other configurations can be designed for quantity requirements.

Price: 4300-064 test set $298, plug-in elements $36-75. Delivery: 4 weeks ARO from *Bird Electronic Corporation, 30303 Aurora Road, Cleveland (Solon) OH 44139.*

GARY MODEL 120 DMM CALIBRATOR IMPRESSIONS

"What good is my new, super accurate digital multimeter if I can't calibrate it?" you might ask, after purchasing such a device. Not a bad question, and considering the popularity of digital meters these days, it is a question that should be addressed.

DMMs are capable of extreme accuracy, which is of not much use when no method of initially calibrating the device is available. The Gary McClellan Company, a manufacturer of DMM kits, has provided the solution to the problem with their Model 120 DMM calibrator.

You may recall that last month I reviewed the Gary McClellan 103 DMM kit, the $29 special. I needed to calibrate that device, as well as my trusty analog meter. McClellan responded by providing the 120 calibrator to review.

The 120 calibrator uses an internal IC to provide voltage references of .1 volt at .2%, 1.0 volt at .2%, and 10.0 volts at .1%. Additionally, resistance references from 100 Ohms to 1 megohm are provided with similar accuracy. The calibrator is housed in a small plastic case with "banana" jacks for output connectors. A push-button enables the device when required, thus saving the internal 18-volt battery, consisting of two 9-volt transistor batteries.

As expected, operating the 120 calibrator is as easy as pushing the enable button. The meter or DMM to be calibrated is set to the appropriate range and adjusted while firing the calibrator. For the first time, I was really confident of the accuracy of my meter. The calibrator is so compact and easy to use that it can be used at a moment's notice — I keep mine directly behind my old VTVM for periodic checks. The decade voltage references also allow meters to be checked for linearity.

All things considered, the McClellan 120 DMM calibrator is a useful piece of test gear — usable by anyone with a DMM or VTVM, which includes just about everyone!

The Model 120 calibrator is priced at $34.95 factory built. *Gary McClellan and Company, Box 2085, 1001 W. Imperial Hiway, La Habra CA 90631.*

THE SNOOP LOOP

Sencore, manufacturers of high quality test equipment, has made available a closed loop for signal pickup and frequency measurements, without connecting to the circuit. The Snoop Loop is simple in construction, as it connects directly to a 50 Ohm input cable for direct application to the new Sencore FC45 frequency counter or the PR47 UHF prescaler. The Snoop Loop works equally well on other 50 Ohm input frequency counters, as it enables the user to "hold back" from any of the high power sources, without actually connecting to the source, as it protects the frequency counter and the operator. Then, too, the PL207 Snoop Loop can be used to "snoop back" all along the signal path all the way back to low level circuits and be placed directly over oscillator coils, for example, without upsetting the operating frequency of the oscillator. The Snoop Loop model PL207, at $9.95, can be purchased from any Sencore distributor, or directly from the Sencore service department in Sioux Falls. *Sencore, 3200 Sencore Drive, Sioux Falls SD 57107, (605) 339-0100.*

POLICE RADAR DETECTOR IN KIT FORM

Now, for the first time, the proven "Bird Dog" police radar detector is offered in kit form. The Bird Dog has been proven by thousands of truckers and motorists over millions of miles. The Bird Dog was designed for long range, troublefree, hands off, reliable operation. Actual tests and reports from truckers and professional motorists show the Bird Dog to detect moving police radar as far away as 2½ to 3 miles. A unit with this type of sensitivity alerts the motorist of police radar long before the police radar has the motorist in sight. In actual comparative tests, the Bird Dog is equal in sensitivity to the top three radar detectors now on the market.

The Bird Dog is usually located on

Remote Speaker Mike for Your HT

I received my Wilson 1402SM HT a few weeks ago and immediately started having a ball mobiling, both on foot and in the car. In using it while in the car, I connected it to the rooftop 5/8 wave antenna. It was a bit awkward to use however, holding it up to my face and using it "a la a great big microphone." The microphone, located close to the bottom on the Wilson instead of the customary position about 3/4 of the way up, didn't help any. In using it while I was walking, I found it embarrassing seeing people driving by and turning to stare as I either held it to my ear in order to hear adequately, or positioning it next to my mouth for transmitting. I'm no youngster so I can't qualify as a kid playing Dick Tracy. I decided that a remote speaker/microphone was an absolute must. A quick check with the ads revealed that I'd have had to come up with $24.00 for a new one. It might as well have been $240.00 as far as my pocketbook was concerned. That left me no choice but to try to home brew one. With my huge junk box I didn't anticipate any parts problem. I live alone in a big house trailer. My friends say that I live in a huge junk box. My junk box served me well, as I had all of the necessary "junk." In my local area, you can duplicate my unit for about $1.50 if you have an old mike to start with. We have a fantastic electronics surplus outlet here for the necessary "junk." It is most unfortunate that he does not handle mail orders.

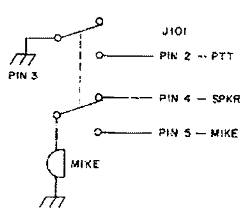

Fig. 1. Using mike as speaker.

At first I tried a dynamic microphone itself as both a speaker and as a microphone. See Fig. 1 for details. Actually, the element was a Shure Brothers controlled-magnetic transducer. It worked, but the "speaker" output was quite low. The output compared to a transistor radio earpiece. I next tried various true dynamic microphone elements of different shapes and sizes. I found one that had usable output, at least while in the trailer, but left much to be desired as a microphone. It made me sound as if I was talking with my head in a barrel. I added a high pass filter between the element and the speech amplifier input, to pre-emphasize the highs. See Fig. 2. The tone quality improved significantly, but the output suffered to the point of requiring my yelling into the mike. I changed the filter configuration to that as shown in Fig. 3, and it sounded normal. I did, however, vary the resistance value so that the deviation level was normal as well. This worked out reasonably well except that, needless to say, in a noisy environment, the "speaker" output was somewhat low and the unit had to be held up to one's ear as with an earphone. Another drawback was that the internal speaker would still "squawk," and consequently I could not operate in quiet environments, i.e., restaurants, libraries, hospitals, etc. Operating mobile on foot didn't work out too well either. I had the unit snapped to my belt and under my jacket, as it was cold out. This necessitated using the "mike" as an earphone continuously as I could not hear the internal speaker at all. Boy, does your arm ever get tired after awhile. Using it in the car wasn't acceptable either. The audio (from the internal speaker) was not loud enough to overcome the din of a noisy truck passing by and I couldn't continually hold the "mike" to my ear and still perform prerequisite driving functions. Oh well, back to the drafting board.

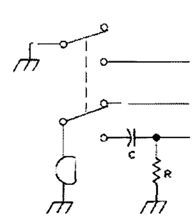

Fig. 2. Using mike with filter.

I then attempted using a small (1½") speaker both as a mike and speaker – the inverse of what I had tried previously. This worked out very satisfactorily as a speaker but not as a mike. Once again it sounded as if I was talking while I had my head in a barrel. The circuit was the same as that of Fig. 1, except that the element was a speaker. Since the deviation was low as well, I added a micro-miniature transistor output transformer to the mike input circuit for proper impedance matching. See Fig. 4. This increased the output to the point of overdeviating. The quality remained bassy. I added a high pass filter as with the dynamic element and got it sounding "hi-fi." The final circuit is shown in Fig. 5.

I can now drape the "mike" over my shoulder, either while using it in the car or while walking with it and it works fine. The audio level is more than adequate to override extraneous noises. The audio level control is now set so low that the raucous racket previously emanating from the internal speaker is now the equivalent of a stout whisper. I used a standard communication hand mike case for my unit. I held the speaker in place using silicone rubber (bathtub caulk). I replaced the push to

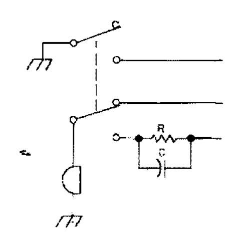

Fig. 3. A better filter for transmitting . . .

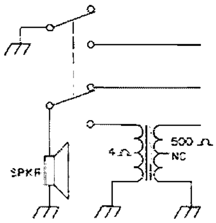

Fig. 4. This one hears well . . .

talk switch (it was only dpst) with a miniature push-button panel mount switch. My speaker/microphone works like a charm, and I've had nothing but compliments regarding how nice it sounds.

If you're wondering why I didn't try a separate miniature microphone, the answer is simply that my junk box did not produce one. I'm glad now that it did not. I did entertain the thought of a separate standard size microphone but could not squeeze one into the mike case along with the speaker.

This means of accentuating the highs (pre-emphasis) to make the microphone sound "human" applies to any microphone element. I even tried it with a carbon mike and now its quality can't be told from a communications type crystal, ceramic or dynamic microphone. Try it with a cheap (home tape recorder type) dynamic and make it sound "hi-fi." The values have to be altered to satisfy the characteristics of your speech amplifier and to compensate for the particular microphone element that you're using. ■

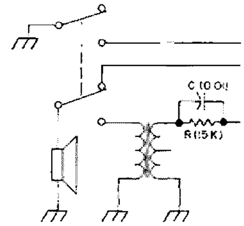

Fig. 5. Eureka! The finished unit.

Split Your IC-22S

-- adding splinter frequencies

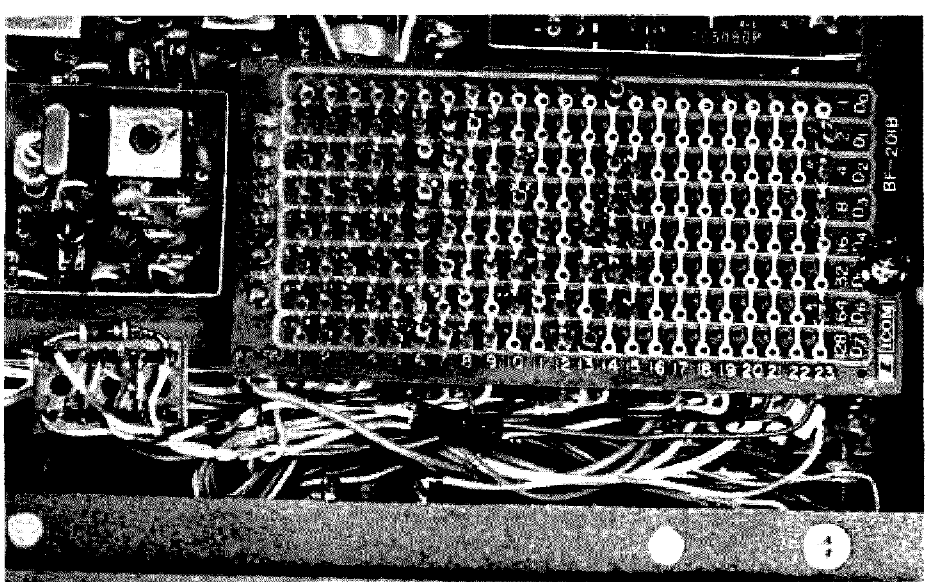
The IC-22S has brought the versatility of a synthesized 2 meter transceiver finally within the reach of those without unlimited funding, apparently by avoiding thumbwheel switches, digital displays, and the circuitry that these devices require. However, it has a limitation shared by most of the new synthesized rigs — it is restricted to operating on a 600 kHz split. In most localities this is no problem, but here in Los Angeles one of the most popular repeaters uses an odd split, receiving on 147.435 MHz and transmitting on 146.40 MHz. Numerous other communities also have this problem.

The IC-22S uses a diode matrix to program its frequency synthesizer for the lower of the two frequencies to be used. The selector switch selects a particular set of diodes. The output of the diode matrix goes to a digital adder circuit which adds 600 kHz (a binary 101000, where the least significant bit represents 15 kHz) when the higher frequency is called for. To modify this circuit would be a tedious job and, in all likelihood, would make it difficult to restore the circuit to its original state should in-warranty service be required. What must be done, then, is to use a different set of diodes for the second frequency.

When I first studied the circuit, I was disappointed to see that the voltage levels used were 0 and 9 volts, which eliminated the use of TTL devices. I was just about to settle for using a relay, but the thought of using a relay in a solid state device left me cold because of the threat of damage caused by transients from the coil. Nine volt relays aren't too easy to find, either. Then I noticed that the logic following the diode matrix was all CMOS, which operates on a supply voltage of anywhere from 3 to 15 volts. My problems were over.

In this circuit (Fig. 1), a CD4001 CMOS quad NOR gate chip provides all the gating necessary. The two inputs are the line from the selector switch and the "dp" line. The "dp," or duplex line, enables the adder circuit and here is used to enable the second set of diodes and disable the first. Both sets are disabled when the channel selector switch is not in the special position. The two outputs go to what I call the "normal" and the "abnormal" diodes. The normal diodes select the frequency to be used when the "dp" line is false (0 V), and the abnormal diodes select the frequency to be used when the "dp" line is true (9 V). In my particular case, because it is desirable to be able to receive on the repeater input for T-hunts or when there is interference on the output, I use the *duplex A* position. This position enables the adder logic ("dp" line true) in the receive mode. Therefore the diodes for receive (146.40 here) must be programmed for 600 kHz lower, or 145.80. Although this frequency is supposedly out of the range of the synthesizer, it doesn't really matter because the adder circuit intervenes before the 145.80 information ever reaches the synthesizer. There is plenty of range in the diode arrangement to program 600 kHz below even 146.01 MHz. Switching the function switch to the *simplex* position allows both receive and transmit on the *normal* frequency.

Construction is fairly simple. I wired everything on the back of a 14 pin IC socket, which fits very nicely between the volume control and the synthesizer board. I didn't fasten the IC socket to anything but just let it float



IC-22S modification. Note pigtailed connection to existing wire to switch in center and new IC socket with sleeve removed at left.

on its wires. This allows removing the diode board and new circuitry as one unit for programming. To insulate the IC socket, I slipped over it a paper tube made from package sealing tape — that's the stuff you have to lick. It tasted dreadful but did the job. The normal diodes occupy the position corresponding to the switch position to be used. At the end of the diode board, adjacent to diode position 22, is an unused position just made to order for the abnormal diodes. To get to the lead coming from the selector switch, unsolder it from the diode board and replace it with the "normal" lead. The positions of the 9 volt and "dp" lines are marked on the board. The only thing missing on the diode board is a ground, and this is available on the meter.

The only problem encountered was rf occasionally getting into the new circuitry and causing loss of lock.

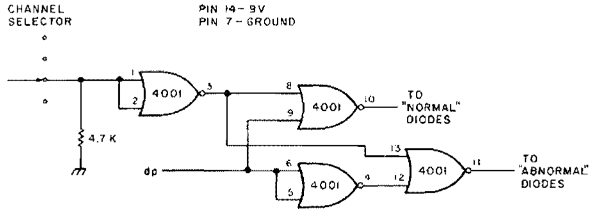


Fig. 1.

Presumably some bypassing would have prevented this, but it was found that there was no trouble whenever the antenna was not actually mounted directly on the radio.

It's great that repeater splits are as standardized as they are, but for those which aren't, this is an easy, inexpensive solution. ■

Remote Monitor for Your Scanner

--complete with lights

This article covers a circuit modification made to a Regency model TMR-8H/LM scanner monitor which replaces the channel indicator bulbs with light emitting diodes and includes the construction of a remote active channel indicator. Material cost for this project is quite reasonable and, depending upon the condition of the shack junk box, should amount to less than $5.00. Light emitting diodes are type MV5026, red, priced at 5/$1.00 just about everywhere. Other than the LEDs, the only parts needed are nine 390 Ohm 2 Watt resistors and a junk box speaker. The technique described should work equally well with other brands of scanners as the circuitry is simple and straightforward.

The scanner in question is (rather permanently) installed in the basement workshop shared by me and my retired fireman father. Most of the fireman's workshop time is spent in pursuit of his hobby at a power jigsaw. Obviously, when the scanner locks on a channel, far too much energy must be expended to turn around and look fifteen feet to see which channel is active. To eliminate this problem, an assembly containing a remote speaker and eight light emitting diode indicators was constructed and mounted on the wall in front of the saw. A labelmaker was used to affix the channel assignments adjacent to the proper LED indicators.

The remote indicators are wired in parallel with the indicators in the receiver. Fig. 1 shows the circuit diagram of the existing control circuitry for one channel.

IC301 is a power NAND gate which when activated by the scan decode circuitry functions such that its appropriate output (such as pin 4 in the figure) becomes a current sink effectively grounding pin 4. As well as activating the channel crystal Y201, the programming circuitry diode CR301 selects the appropriate high or low band mixer and at the same time must sink 120 mA just to light the channel indicator bulb. Not wishing to see if the additional 35 mA drawn by the remote LED in parallel with the No. 53 bulb would be the straw that broke the camel's back, it was decided to replace the bulbs with LEDs.

It is claimed by some scanner-owning visitors that with the LED indicators on the receiver, the locked channel is easier to determine at a quick glance because of the more point source light characteristics of the device.

To install the LEDs is as simple as replacing each light assembly. After removing the bulb assembly, it is necessary to use some method of supporting the diodes. This turned out to be mechanically simple though electrically redundant. As shown in Fig. 2, one end of a 390 Ohm 2 Watt resistor was connected to the +13 V B+ line on the circuit board.

The body of the resistor was positioned facing the opening in the front panel. The anode of the LED was then carefully soldered to the panel end of the resistor while the cathode was soldered to the appropriate contact on the channel lockout switch (same point as the removed bulb). The LED was aligned in the panel opening and that's all there is to it.

The remote installation is quite simple. A cable or wire bundle or whatever you choose to call it is required, and contains a pair of wires for the remote speaker. These may be connected directly to the remote speaker terminals on the rear of the receiver chassis. The cable which can be routed through an existing opening in the rear of the case must also contain an extension of the +13 V B+ line and a control wire for each channel indicator. These control wires are connected to the respective channel lockout switch previously described. Rather than be restricted by a hard-wired cable, I mounted a jack on the back of the chassis and a plug on the cable. (This would be up to individual

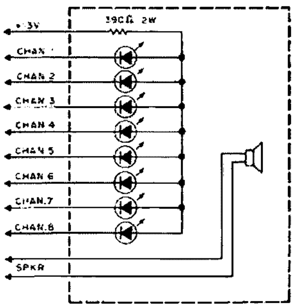

Fig. 3. All LEDs MV5026.

preference.) A circuit diagram of the remote unit is shown in Fig. 3.

Construction of the remote unit can take just about any form which is consistent with your abilities as a carpenter, cabinetmaker, sheetmetal worker or tin knocker. Mine is quite simple, being made out of some kind of fibrous pressboard material which makes friction fitting of the LEDs possible as a method of securing. A Dymo-maker was used to label the appropriate cities and towns beside each indicator using the "clever" scheme of red tape for fire departments and blue tape for police departments.

Having an installation such as this in the same area as the receiver might seem like overkill; however, it could be located upstairs in the kitchen, den or headboard of the bed. Mounted at the end of a hall, it could give one the feeling of being on final approach to an airport runway at night.

In conclusion, the intent here was to start the reader thinking of ideas for custom scanner installations. Putting the receiver on a good outside antenna usually pretty much dictates where the radio must be mounted and left. This restriction, however, should not dictate where you must be to listen to the local activity. ■

Electronics Study Guide

-- remember when...?

There's no doubt about it. Some of the most delightful observations about electronic communication have been scrawled on tablet paper by grade school youngsters. Having taught in public schools for nineteen years, I'm sure of it. Take these historical explanations, for example.

Question: "When was the radio invented?" Answer: "On page 24."

"The radio was invented in the pre-me times."

"The Romans did not have radios. They used smoke signals in both the A.C. and D.C. times."

Kids have a knack for discarding everything but what they consider to be the most essential information. One boy brusquely wrapped up all of man's yearnings, struggles and triumphs in this eight word package: "Progress was from electricity to radios to now."

Here's a remark as charming as childhood itself: "I was thinking the radio was invented before the telegraph. When I learned different, all the thoughts I was going to say went in a swallow down my throat."

Another tiny historian concluded: "The Dark Ages lasted until the invention of electricity."

Through the years, the grade schooler's fund of knowledge has proved to be a glittering gold mine of wit and unconscious wisdom, often unhampered by hard facts. Each new subject seems to be a fertile new field for off-base interpretation and lopsided logic. Digging into facts about Marconi produced such notable nuggets as these:

"Marconi was born in 1874, supposably on his birthday."

"It took much hard work for Marconi to think out how to invent the radio. He had to keep thinking around the clock, twelve days a week."

"In just a few short years he became a sensation overnight."

"He expired in 1937 and later died from this."

Last year a bright-eyed little radio enthusiast came up with this endorsement: "Every time I think how the radio gives us so much fun, I have joy feels all over."

A skeptical classmate of hers absorbed all the statistics regarding the number of ham radio operators in America, but got his skepticism across in one crushing statement: "The total amount of ham operators in America today is more for saying than believing."

It must run in the family. Two years later his younger sister reported: "The number of ham operators we have today is an adsurbly large fact of a number."

The subject of hams has stumped many eager young scholars. Here are three more futile but imaginative explanations:

"Ham operators look something like people."

"They are one of the chief by-products of electricity."

"The meaning of them has a very short memory in my mind."

The elementary school youngster's mind seems to be a vast storehouse of miscellaneous misinformation — half true, half false and wholly delightful. His fund of knowledge about electricity includes such fascinating items as these:

"Electricity has been with us forever and maybe even longer."

"Would the average person be able to keep up with the news if it was not for electricity? The chances are 999 out of a hundred."

"In electricity, opposites attract and vice versa."

"If you see lightning, no you don't. You see electricity."

"From now on, I will put both gladness and wonder in my same thought about electricity."

Here's one I've been trying to figure out for five years: "You should always capitalize the word electricity unless it is not the first word in the sentence."

This next little girl seemed to be giving it all she had when she wrote: "Correct my being wrung, but tell me true or false. Do negative charges go through electrons or through protons? I wrecked my brain trying to think which."

But I'm afraid others are more nonchalant in their pursuit of knowledge: "Protons are bigger than electrons in case I ever want to know."

Psychologists tell us that half learning a fact incorrectly is often the first step to learning it right. So let's be philosophical as we buzz through these fractured facts about electrons and protons:

"100 electrons equal 1 radio program."

"When the switch is on, electrons are constantly bumping into each other inside the wire. There is really quite an overpopulation of electrons."

"Once I saw in an educational cartoon about how electrons move. Electrons are very interesting folks. All their ways are hurry ways."

"Electrons carry the negative charge while protons take the affirmative."

"Electrons are the same as protons only just the opposite."

"I think I admire the electron more than anything else about electricity because it weighs only about one over 2000th as much as a proton but can still hold its own."

Obviously, one of the fringe benefits of being an elementary school teacher is the possibility that the next paper I read will contain a wrong answer that is twice as witty or thought-provoking as the expected one. Sometimes they don't know and they know they don't know, but that doesn't keep their answers from being charming:

"Ideas about how radios work have advanced to the point where they are no longer understandable."

"Did I pass the test about how to get a ham radio operator's license and why not?"

"I have found radios to be easier to listen to than to tell how they work."

Take three small boys, mix

them up thoroughly with several pounds of strange facts, then shake them up with an examination and you have the perfect formula for instant confusion. Here's what I mean:

"The way vacuum tubes work, as I understand it, is not very well understood."

"Many questions have been aroused in my mind about vacuum tubes. As a mattery fact, the main trouble with vacuum tubes is that they give more questions than answers."

"In electricity, positives are attracted by negatives for the reason of search me."

Judging from the size of the handwriting, this next tyke was under the influence of John Hancock when he took time out to report (with the aid of a bright purple Crayola): "When they asked my brother if he would like to watch a ham operator, he rolled his eyes and flashed his teeth and said sure."

Often a grownup can only envy the simplicity of a child's way of expression, as is the case of the lass who remarked: "When I learned we were going to see a movie about ham operators all over the world, I told my feet to quiet down but they felt too Saturday to listen."

In their world of uncertainty, once they know a fact for certain, they hang on to it tenaciously, e.g.: "Another name for the radio is radiotelephony, but I think I will just stick with the first name and learn it good."

Children, like mountain climbers, must always make sure that their grasp on a fact is firm, even though they want to leap far beyond. Otherwise, they may find themselves trapped on a mental ledge called a boner. There is usually at least an element of truth in the most absurd answer. Sometimes they aren't wrong at all. It's just the way they put it that's so funny:

"Radio has a plural known as mass communication."

"Water scientists have figured out how to change river currents into electric currents."

"The best thing live wires are good for is running away from."

"Quite a bit of the world's supply of electricity goes into the making of ham radios."

"Many things about electronic communication that were once thought to be science fiction now actually are."

Members of the grade school set certainly have their own opinions, and few are hesitant to express them:

"All the stuff inside a ham radio is so twisted and complicated it is really not good for anything but being the stuff inside a ham radio."

"Electronics is the study of how to get electricity without lightning."

Then I don't suppose I'll ever forget this remark by another boy: "Last month I found out how a radio works by taking it apart. I both found out and got in trouble."

And you can't argue with the young fellow who reported: "When currents at 110 to 120 volts go through, them radios start making sounds. So would anybody."

When members of the grade school set turn their attention to the subject of vacuum tubes, youngsterisms come as thick as chalk dust. Just what is a vacuum? Here are five answers, fresh from the minds of nine-year-olds:

"Vacuums are made up mostly of nothings."

"A vacuum is an empty place with nothing in it."

"Vacuums are not anythings. We only mention them to let them know we know they're there."

"There is no air in vacuums. That means there is nothing. Try to think of it. It is easier to think of anything than nothing."

"A vacuum tube contains nothing. All of its parts are outside of itself."

Another lad wrote of this frustrating experience: "I figured out how a vacuum tube works twice but I forgot it three times."

One of his classmates reported: "When I learned how empty vacuum tubes are, I would have fainted if I knew how."

If you're at all hazy about other parts in a radio, hang on. These next thoughts will leave you only slightly worse off than before:

"An electron tube can be heated two different ways. Either Fahrenheit or Centipede."

"When you turn a radio on, the tubes get hot. The hotter anything gets, the faster the molecules in it move. Like if a person sits on something hot, his molecules tell him to get up quick."

"In finding out that radio tubes get hot, the fun is not in the fingers."

"Transistors are what cause many radios to play. Transistors are a small but important occupation."

"We now have radios that can run on either standard or daylight time."

One of my students last year had many tussles with his spelling book. When he finished writing one particular sentence, the battleground looked like this: "Termanuls do not agree with themselves spelingly and pruncingly."

With apologies to Mr. Webster, I would like to present a pocket-size dictionary of pint-size definitions, compiled from school children's reports. Should any of them prompt Webster to turn over in his grave, he would have to do so with a smile:

"Axually, a *choke coil* is not as dangerous as its name sounds."

"*Electromagnets* are what you get from mixing electricity and magnets together."

"Think of a *volt*. Then yippee, because now you have had the same thought as Voltaire, after who this thought was named."

Another lad had the right information, but the wrong answer: "There are some things about electricity we are still not sure of. These things are called *whats.*"

If the kids don't know all the answers, they can always do what their parents once did — try to slide by on a guess or two:

"A *radio telescope* is a thing you can hear programs by looking through it."

"*Current electricity* is electricity that is currently in use."

Kids are so full of questions, they can't possibly wait for someone to tell them all the answers. That's why they plunge recklessly ahead on their own, like so:

"Sound travels better in water than in air because in water the molecules are much closer apart."

"I have noticed that if a portable radio is turned in different directions, the station talks loudest behind its back."

"Although air is hollow it is not just for looking through. It is also for having radio waves running through it and trying to answer questions about."

"Radio waves would not be all that important to study if it were not for ears."

"Someone in here said that FM has shorter waves than shortwave radios. Is this so? I think it is because I think I was the one that said it." (If you can't believe yourself these days, who can you believe?)

An obviously more confident young man proclaimed: "Much has been said about how radio waves travel. Radio waves are both hearable and talkable."

Another moppet was going great, until the last word: "I believe the radio is one of the most important inventions of all time. Of course my father works at a radio station, so I may be a little pregnant."

That's one young writer who would have done fine if she had just stopped while she was ahead (which is good advice for grownup writers, too). ■

Low Cost Tone Decoder

-- for repeater control

Chris Winter WB0VSZ
2040 Glass Road NE
Cedar Rapids IA 52402

The usefulness of the Bell touchtone™ system for remote control, and especially for remote control of repeaters, is well known. The cost of touchtone decoders is quite low now, chiefly because of the Signetics 567 tone decoder

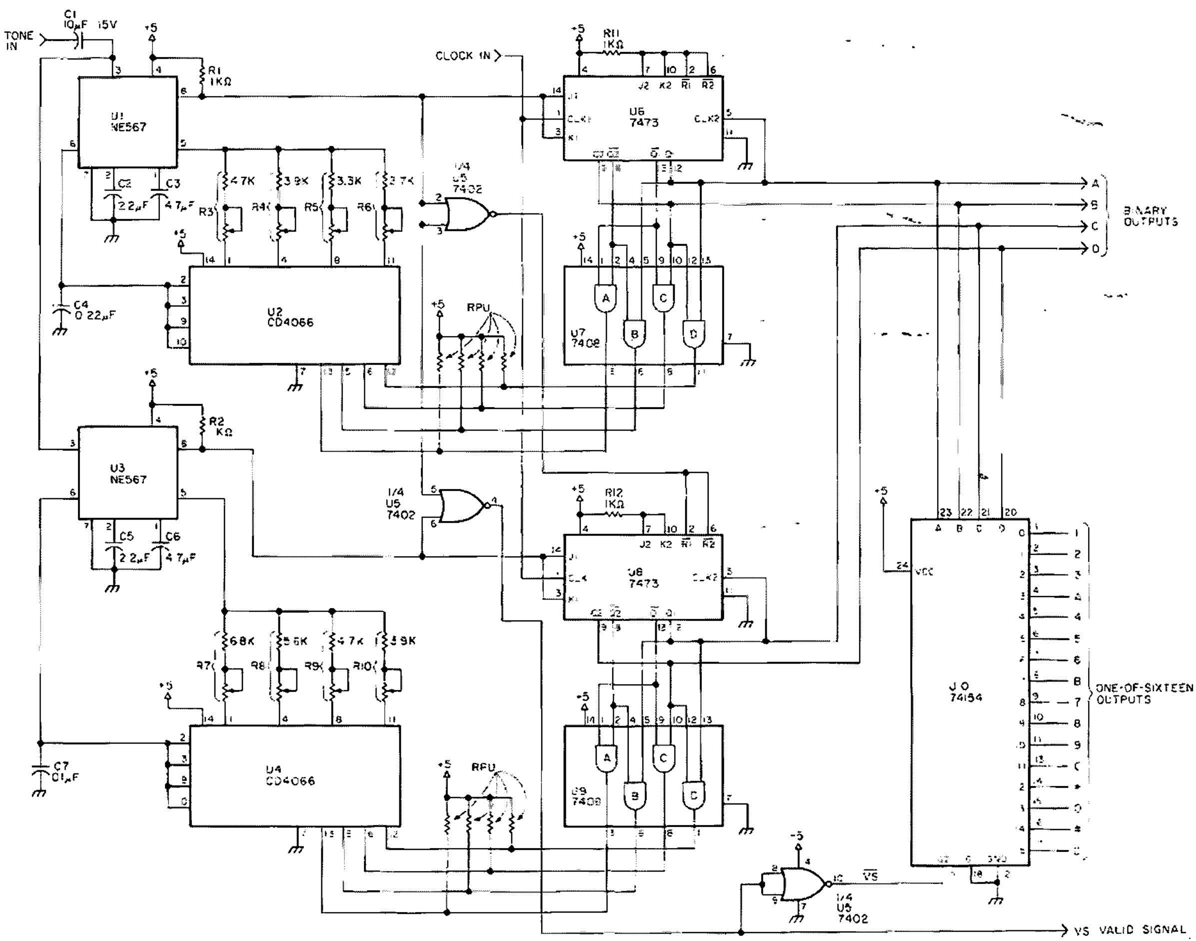

Fig. 1. Decoder circuit.

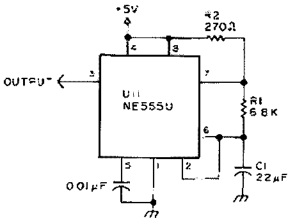

Fig. 2. Basic clock circuit.

IC. However, you still need eight of these ICs for a full 16 button system, if you use the standard method as described in *Signetics Databook.*[4]

A scanning decoder can get by with only two tone decoder ICs. It can become so complex, though, that any cost saving is wiped out. I decided that a scanning decoder would be simple enough to be worthwhile. My version is similar to the one described in reference 3. It uses a pair of 567s, a 555 timer, 2 CMOS quad switches, and 6 TTL ICs. All of these ICs are readily available from suppliers who advertise in *73.* The total cost of the ICs should be under 10 dollars. In addition, the decoder uses a handful of resistors and capacitors.

Circuit Operation

Fig. 1 shows a schematic diagram of the decoder. The eight tones used in the Bell system are divided into two groups. The low group tones – 697, 770, 852, and 941 Hz – are referred to as L1, L2, L3, and L4. H1, H2, H3, and H4 are the high group tones, respectively – 1209, 1336, 1477, and 1633 Hz.

U1 decodes tones in the low group. Its frequency of operation is determined by C4 and one of the resistors R3-R6. The resistors are connected in succession by U2, a CMOS quad switch. The state of U6, a dual flip-flop, is decoded by U7 into four control lines. One of the lines is always high, closing one of the individual switches in U2. The frequency of U3, the high group decoder, is switched the same way.

With no tone present, U8 is held reset while U6 is continuously clocked. When a pair of tones appears, as soon as U1 is switched to the proper frequency, U1-8 goes low. U6 is held in its current state, and U8 is allowed to clock. Then when U3 has decoded the high tone of the pair, its output goes low. U8 stops clocking and the valid signal line goes high. This indicates that the detection process is complete.

The flip-flop outputs are combined into a four-bit binary representation of the tone code. This four-bit word also goes to a 74154, which gives a low on the selected one-of-sixteen output. When the valid signal line is low, U10 is disabled – all outputs high.

Construction

There are no special problems in constructing the unit. Layout is not critical, and the wiring is not extremely complex, so a PC board is not essential. Follow the normal precautions in handling the CMOS ICs, and do not omit the eight pullup resistors (labeled RPU in Fig. 1). They protect the CMOS gates if the 7408s are removed for any reason. IC sockets make troubleshooting a lot easier, but are not necessary.

Some Notes on Design

The basic timer circuit (Fig. 2) is derived from reference 4. The values of R1 and C1 give a frequency in the neighborhood of 4 Hz. R2 is chosen for a duty cycle of 50%.

Fig. 3 shows some changes to the clock circuit, which make troubleshooting and alignment a lot less of a hassle. First, in order to set the frequency control resistors, it's best to defeat the cycling action and leave the proper CMOS switch permanently on. This is the purpose of S1. It converts the 555 from astable to monostable operation. Then, each time S2 is pressed, the 555

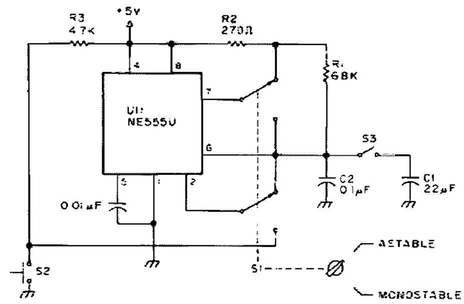

Fig. 3. Modified clock circuit.

produces a single pulse, and the state of the flip-flop advances by 1. To complete this revision, add a switch to ground pin 8 of U1. Some LED indicators driven from the four output lines are also handy. S3 simply lets the timer run fast enough so that the waveforms are easily viewed on a scope.

If, unlike me, you don't like to add a lot of extra hardware just to ease setup, you can get the same results with a couple of jumpers. The method is explained in the section on alignment.

The eight pullup resistors can be any convenient value between 10 kilohms and 1 megohm.

I used multi-turn pots to set the frequencies of U1 and U3. Assuming C4 and C7 are exactly 0.22 and 0.1 uF, you can calculate the resistance values from an equation in reference 4. These values are shown in Table 1. I used 5 kilohm pots in series with fixed 10% resistors. If you choose to set the frequencies with combinations of fixed resistors (more work but less strain on the budget), Table 1 gives you starting points. Note that the values given don't take into account the series resistance of the CMOS switches. There are two types of switches you can use: The CD4016 costs less, but I recommend the CD4066 because of its lower "on" resistance. You might also want to use more accurate capacitors for C4 and C7.

In a standard decoder as shown in reference 4, the ICs will lock up very quickly. Lockup times less than 0.1 second are easily achieved. With a scanning decoder, however, you cannot count on decoding a pair of tones in less than 8 clock periods. It takes this long for both counters to cycle through their four possible states. Each clock period must be long enough for the vco to settle down, then lock onto the tone. Because of this, there is little need to optimize the lockup time, and the design is simpler. You only need to be sure that the detection bands for the various tones do not overlap. Bandwidth is reduced by increasing the values of C2 and C5, and C3 and C6. I found that the values shown in Fig. 1 gave a narrow enough bandwidth. You may find that the high group bands overlap, especially H3 and H4. If so, change resistor values to move the bands apart. A high input level will increase bandwidth. Keep it as low as possible.

Alignment

A good audio generator – one with an output level control and an accurate frequency dial – is needed to align the decoder. You'll find that a scope and a frequency counter will be very useful.

I'm going to assume that you've built the circuit on "anyboard" without using IC sockets or any of the frills described in the section on design notes. I'll also assume that you used fixed resistors for R3-R10. If you use pots, the procedure is almost the same.

After checking for wiring errors, apply power and

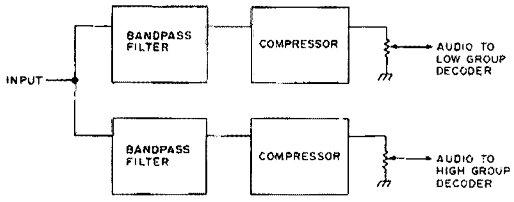

Fig. 4. Block diagram of input conditioning scheme.

measure the current. The decoder should draw about 250 mA. Be sure that U11 is producing a square wave at about 4 Hz. Then check that U6 is clocking normally and that pins 13, 5, 6, and 12 of U2 go high in succession. Now connect a jumper to U1-8, and touch the other end to ground. This will stop U6, leaving one switch of U2 closed. The trick is to get U2-13 high, closing the switch for the L1 resistor. This will take a few tries.

Once you have U2-13 high, leave U1-8 grounded and connect a decade box from U1-5 to U2-1. Set it to the value given in Table 1 for the L1 resistor. Connect an audio generator to the tone input. Set the frequency to 700 Hz and the level to 0.2 V rms. Remove the jumper. U1-8 should remain low. If it does not, adjust the decade box as necessary until it goes low. Remember to wait 1 second (four clock periods) between resistance changes. To fine tune the value, approach it from above and below and note the values where U1-8 just goes low. Set the decade box halfway between them. Now lower the audio level to about 50 mV rms. It's best to use the lowest level that will activate the decoder. Repeat the fine tuning process. This gives you the final value for R3. Select R4, R5, and R6 the same way, connecting the decade box in series with the proper switch each time. Now ground U1-8 permanently with the jumper. U4 should start switching. Use another jumper from U3-8 to ground to set the proper switch of U4 on, and select R7-R10. Wire the resistors into the circuit and remove the jumpers.

Check decoder operation by setting the generator to various low group frequencies. The circuit should hold in the proper state each time. Ground U1-8 and check the high group decoder.

If you have access to a frequency counter with a high input impedance, you can use an alternate method to set up the decoder. Connect the counter to pin 6 of U1 or U3. Select resistors so that the vco runs at the tone frequency in each case. This method saves some time and makes it easier to set single-turn pots.

This completes the alignment. Use a touchtone pad to check that the binary and one-of-sixteen outputs are corrrect as shown in Table 2. The decoder is now ready for operation. There are some pitfalls to avoid in making it work in your system, however.

Interfacing the Decoder

The ideal input signal is a pair of sine waves. Most touchtone pads use digital techniques to generate the tones and do not produce sine waves. With these signals, the decoder needs a higher level than it would with sine waves and does not respond quite as quickly. Due to line losses or receiver audio response, the tones of a pair may not be equal in amplitude. Also, noise and distortion can cause false outputs. The best prevention for these problems is to use bandpass filters followed by compressors for both the low group and high group tones. The block diagram of such a system is shown in Fig. 4. These problems are discussed in more detail in references 1 and 2. A delay circuit like that shown in reference 2 can help prevent falsing. Of course, if you want to drive loads drawing more than a few mA, you will need transistors and perhaps relays.

Finally, take a look at Table 2. As you can see, because of the way the touchtone keyboard is organized, my decoder cannot produce true BCD outputs. The keys are encoded and decoded in rows from top to bottom: 1, 2, 3, A, and so on. There are possibilities in using a touchtone pad to control a home computer, but it would take some code conversion hardware.

Conclusion

The scanning touchtone decoder I've described uses a small number of ICs and requires only a single 5-volt supply. While it is slower than the standard type of decoder, it is reliable and uses readily available parts. It compares favorably in price with the standard decoder. It has fairly good immunity to noise and distortion and is easily protected if these are a problem. Keep its limitations in mind and you will get good service out of it. ■

Tone frequency	Capacitance (chosen)	Resistance (calculated)
697 Hz	0.22 uF	7.174k Ohms
770 Hz	0.22 uF	6.494k Ohms
852 Hz	0.22 uF	5.869k Ohms
941 Hz	0.22 uF	5.313k Ohms
1209 Hz	0.1 uF	9.098k Ohms
1336 Hz	0.1 uF	8.234k Ohms
1477 Hz	0.1 uF	7.448k Ohms
1633 Hz	0.1 uF	6.736k Ohms

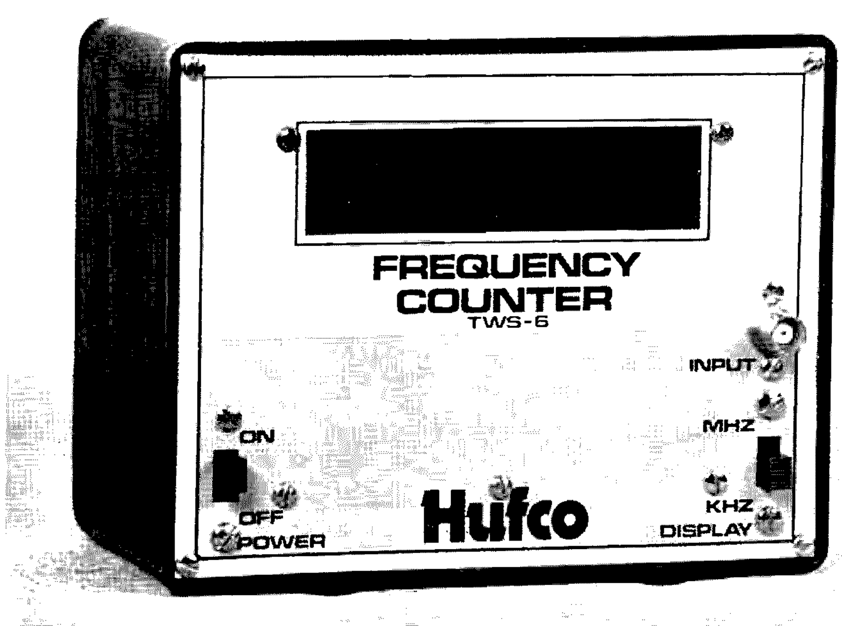
Hufco Counter Kit

-- report from a happy user



Fundamentally, basically, and first of all, I'm cheap. If there is a cheaper or less expensive way of doing something, I'll try it. Perhaps that's why the Hufco "Easy $25 Counter Kit" caught my eye (my eyes are located in my wallet).

After painfully shelling out the coin and placing my order in the mail, I settled down for a long wait. Wonder of all wonders, within a week I received an acknowledgment of my order and a note that it would be six weeks for delivery (who *ever* acknowledges orders nowadays?). Included with the note was a list of the parts required for the kit so I could start "acquiring" the parts.

Perhaps this is the time to explain that this is a rather unique "kit" in that it does not include any parts . . . just the PC boards, a precut cabinet for the counter, and an instruction manual.

Through the abundance of an overstuffed junk box and the cultivation of friends, most of the parts were gradually collected. One traumatic experience was having to order the XAN362 readouts. The only readouts suitable were installed in a friend's clock, and he adamantly refused to part with them (cheap!).

After six weeks of waiting, the counter didn't come, but I did receive a nice letter explaining about the delay -- UPS strikes, delayed shipments from suppliers, etc. I also received a complimentary copy of their new publication *Channel 51*. This rather well done magazine is obviously aimed at CBers who wish to convert to ham radio. This gesture made the following weeks of waiting more palatable, just knowing that someone somewhere knew that I had an order coming.

Sure enough, one day a package arrived, and I was able to inspect my new TWS-006 counter kit. The cabinet was extremely well built with a nice silk screened front panel reminiscent in color of the old Heathkit

brown and beige.

The PC boards were the biggest surprise. I had expected rather rough boards at that price. Not so.

These were double-sided boards with plated-through holes. Clear sharp traces gave plenty of room for even the klutziest soldering iron mechanic. The component placement is clearly screened on the boards, and the one small mistake (a reversed index mark for one of the 7447s) is clearly called to your attention in the manual.

While the manual itself is not quite what I'd call Heathkit quality, it is adequate to insure correct assembly. It not only gives a step-by-step procedure for assembly and interconnections, it also gives a good presentation of the theory of operation and a method of troubleshooting in case of any malfunction. Various options are discussed, including adding a prescaler for VHF or UHF operation. I ended up purchasing their prescaler board ($4.00) for future addition.

The only drawbacks I ran into during construction are quite minor. The resistors used for the layout must have been 1/8 Watt units since my 1/4 Watt resistors were somewhat oversized. This resulted in a less than picture perfect board when finished, with leads wrapped back under components. Also, I'd like to know where they found 3/8" diameter 1000 uF capacitors on their silk screen layout. Mine are larger, but by extending leads, I was able to fit them in. These are all cosmetic complaints and don't affect the assembly of the unit.

The actual smoke testing of the unit was very disappointing ... it worked. I couldn't believe it ... I just plugged it in, and it worked ... very anticlimactic. Other than adjusting the trimmer for exact frequency, there were no other adjustments or tuning required. Unless you've built a lot of kits before, you can't realize just how frustrating this can be. Half of the fun of kits is in troubleshooting the darn things after you've built them. I remember one clock kit that was over six months of fun ... but that's another story.

The unit isn't the most sensitive I've ever seen, but it's not that bad either. I was able to trip it at less than full output from my Measurements Model 80 signal generator all the way up to 57 MHz. By picking and selecting 74LS90 ICs for the first three decades, I was able to bring the sensitivity down somewhat, but even as-is it is quite usable. I was able to read my 25 Watt CW transmitter on 21 MHz from across the room with just a clip lead as a probe.

Accuracy seems to be as good as six digits will allow. It counts the crystal output from my BC-221 as 2.00001 with the last digit varying from 1 to 2 to 0 on alternate counts. Warmup does not seem to affect it at all.

Options that I plan to add to my counter are nicads for portable operation and the prescaler as soon as I can scrounge up a 95H90 chip for it. The company also offers an optional input which features the ability to "withstand the full unloaded output from a transceiver on 28 MHz for 20 minutes." Since I already have a dummy load, and rarely load my transmitter into my counter, I don't plan on adding this option. Oh yes, it also increases the sensitivity to some extent or something like that.

In conclusion, I would recommend this counter to anyone who has a need for a *cheap* counter, or to anyone who is *cheap* and needs a counter. Seriously, it performs as well or better than commercial counters costing several times as much. If you have a well stocked junk box (or a friend who has one), you can bring the cost of this counter kit to well under $40 and still have the convenience of a well designed kit. ■

pass along your experience through the pages of *73* ... write.

One of the reasons ham equipment has been in such short supply has been the drain of sales to HF CBers. Many of the ham dealers are selling Yaesu and Kenwood transceivers to CB dealers (usually after converting the rig to work on the 27 MHz band). These dealers sell the rig to a CBer at the full list price (or more), often complete with an amplifier.

A few dealers make every effort to see that this ham gear does not end up in a CB shack — with Tufts Electronics being one of the leaders in this crusade. The manufacturers and importers of ham gear are unable to stop selling to the dealers who are abusing us, due to restraint-of-trade laws. There has been a move to get dealers to demand proof of a ham ticket before making a sale, but this won't cure anything, because the dealers who are selling ham gear for CB use know damned well what they are doing and are not about to stop as long as they can make an extra buck this way. If you can figure out any workable scheme to make it unprofitable to sell to CBers, then you'll have a good plan to stop this practice.

In the meanwhile, let's be vigilant and keep the CBers from twisting the dials of their transceivers to a ham band. What they do on the 27 MHz band is honestly none of our business at present — and we may be better off in the long run because they have established such a strong foothold there. What if the ITU (WARC) conference actually turns out as most of the knowledgeable hams of the world are predicting ... with the loss of all HF ham bands? In that case, the 27 MHz HF CB band may be the *only* HF "ham" band we've got left.

THIRD ANNUAL INDUSTRY MEETING

The 1978 ham manufacturers and dealers conference will be held in Aspen, Colorado, from January 8th to 15th. In addition to the usual breakfast and dinner meetings which have made this yearly conference such a success, there will be three forum workshops. Chuck Martin, the owner of Tufts Electronics, will conduct a workshop on things store managers should know, such as how to sell ham equipment, how to develop a comprehensive line of equipment to sell, and how to drum up a lot of local business using catalogs, newspaper advertising, radio, and television.

There will also be a workshop on how to write ads, catalogs, and other sales literature. This will also include a comprehensive workshop on media selection and planning: how to plan your advertising budget, how to select an ad agency, and how to save substantially on your advertising. This workshop could well pay for the entire conference.

Each of the workshops will probably take two evenings due to the comprehensiveness of the material. Even the old-timers will find a lot of value in these workshops.

There will be a forum devoted to crystal ball-gazing — second-guessing the future so you can take maximum advantage of what is going to happen next year.

The conference will be convening at the Continental in Aspen — it's a little tacky, but it does have a nice heated pool and a sauna, and it is right in the heart of town. Accommodations go early, so if you want to take advantage of this third annual ham industry workshop, better make your reservations with the hotel. There may even be snow this year.

SOME OPENINGS AT 73

It should be no news that *73* is growing — and so is *Kilobaud*. This means that we need more people to work on the magazines and the other plans afoot. We do have a need for some hams with experience in writing and construction to help test new equipment and write it up ... to work on books ... help with articles ... etc. This is something that really has to be done right here in New Hampshire, which is one of the nicest places in the country to live.

We also need help in working on microcomputers ... testing programs and selling them ... checking out the newest equipment ... things like that. A ham with a lot of experience in FORTRAN IV would find some interesting work. We also need help in support jobs such as management, marketing, sales, etc.

We're looking for people with intelligence, with some background, who don't smoke, and who are willing to go all out to become tops in their jobs. The pay is reasonable, and can be most rewarding if an outstanding job is done. Working for a small firm such as this gives you an excellent opportunity to grow and learn ... something you just can't get in a larger business.

All you have to do is look at some of the *73* graduates ... one is editor of a well-known magazine ... another

A Single Tone Can Do It

-- simple tone control system

In the process of putting together a repeater of my own, I found that I wanted to perform a simple ON/OFF auxiliary function via the repeater input. In my case, it happened to be turning an aural frequency indicator on or off, but the function could be almost anything. From previous experience with such a used control in another location, I decided on the use of two single tones – one to turn the function on and one to turn it back off. Armed with this idea, I dug into my data books, experimented a little, and arrived at the circuit described in this article.

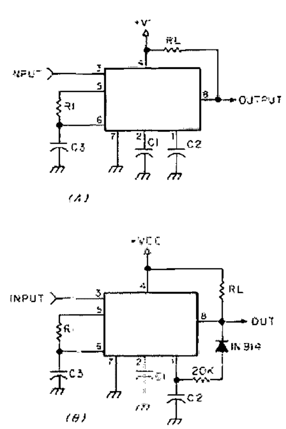

Fig. 1. (a) Basic 567 decoder circuit. Resistor R1 and capacitor C3 set the basic operating frequency or detection frequency. C1 and C2 are loop filters and their values affect response time and detection bandwidth. (b) Latching circuit, feeding the output (pin 8) back to the input of the final stage (pin 1). The latch can be released by pulling pin 1 to Vcc momentarily.

Circuit Operation

The basic 567 decoder circuit is shown in Fig. 1(a). By feeding the output back to the last stage at pin 1 (output filter), the output can be latched on. The circuit can then be unlatched simply by pulling pin 1 high momentarily. A general purpose PNP transistor can be hooked-up to do that task.

I then added another 567 decoder to get the unlatch signal. The output of this decoder turns on the PNP transistor just mentioned, thus unlatching the circuit.

The complete circuit is shown in Fig. 2. With the values shown, the decoders should tune over most of the normal single tone range. Depending on the length of tone burst available, the values of C3, 4, 6, and 7 might have to be adjusted slightly if the decoder does not respond fast enough.

Adjustment

When wiring is complete and checked, then power can be applied and the circuit checked out. A frequency counter or accurately calibrated scope is necessary to adjust the center frequency of the 567 decoders. Attach the counter or scope to pin 5 of U1 and then adjust R1 for the desired "ON" frequency. In my case, I used 1800 Hz. Now put the counter (scope) on pin 5 of U2 and adjust R4 for the desired "OFF" tone. Again, in my case, I used 1950 Hz.

Now connect whatever load you intend to use to pin 8. I have shown a relay since that is the most common usage. Connect an audio generator to the input and apply about 100 mV of 1800 Hz audio. The relay (load) should activate and should remain activated when the tone is removed. Now set the audio generator to the

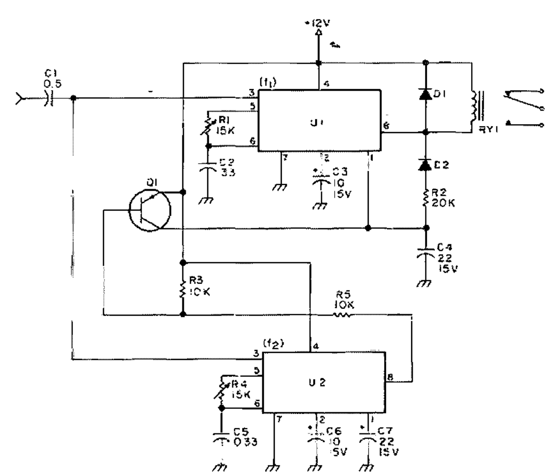

Fig. 2. Complete schematic of the two tone latching decoder.

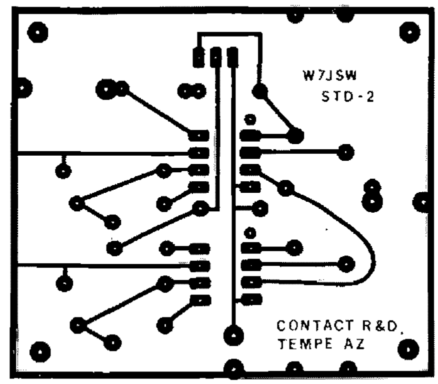

Fig. 3. (a) Parts layout for the prototype printed circuit board. This is the parts side of the board; the copper is on the other side. (b) Full size PC pattern for the prototype circuit board. Production boards, available from CONTACT, Inc., 35 W. Fairmont Dr., Tempe AZ 85281, will probably be slightly larger to make parts placement easier.

"OFF" frequency (1950) and apply that to the input. If all goes well, the load should de-activate.

Operation

I have my decoder operating from a 12 volt line and I am using a 24 volt relay as the load. The repeater receiver audio is fed to the audio input and I use the relay contacts to turn my tone frequency indicator on/off. The only thing you have to watch pretty closely is the input level to the 567s. The best operating point is about 150 mV. More will cause falsing and less won't operate too reliably.

Conclusion

A layout for a printed circuit board and the parts arrangement are shown in Fig. 3. The board is available from CONTACT, 35 W. Fairmont Dr., Tempe AZ 85281, for $5.00 ppd.

With cross-banding now approved, I may put one of these circuits on one of our local repeaters to provide a user accessible cross-link between 450 and 2 meters. Good luck and write if you have questions, but with today's postal rates, please enclose an SASE if you want a reply. ■

from page 183

is the ad manager of a new magazine and is reportedly pulling down over $100,000 a year . . . another has his own magazine now, which is worth over $1 million . . . etc. The line forms to the left.

NEW IDEAS NEEDED

Despite the sudden growth of amateur radio as a result of the club programs to get in new licensees, attendance at hamfests seems to have been dropping off. How come, with more hams than ever before, we have fewer going to hamfests?

There are probably several reasons . . . such as the high cost of getting into hamfests . . . a lack of any real promotion of many of the events, with more dependence on prizes than anything else to draw attendance. The recent ARRL event at Hartford, home base for the League, is a case in point. The show was well-organized, and promoted in *QST* . . . yet the turnout was disappointing. The $6.50 entrance fee was cited by many as prohibitive for the youngsters . . . and, indeed, there were very few kids running around the show. Most of the fellows I saw were chaps I have known for thirty or forty years.

You really can't expect to get $6.50 from kids to see a dozen or so exhibits (mostly by dealers trying hard to sell gear) plus a talk by Dannals. Oh, add $20 if you want to take in the dinner.

We need ideas. If you have some ideas that have worked with a hamfest in your area, why not put them down on paper and send them along so the rest of us can benefit? We'll try to get all the good schemes published in *73*.

CB TO TEN

Owners of Standard Horizon 29 CB rigs can rejoice, for Standard has a dandy ten meter conversion for the set. If you have the 23-channel set, as I have, you can get a 40-channel switch from your local Standard dealer and get 40 channels on ten meters.

Standard has a conversion sheet available, "Procedure for 10 Meter Conversion of Horizon 29." This gives the details of where to cut the foil on the board and what parts to add and change. The changes are minimal.

The result is a rig which works on ten meters, starting at 28,965 and going up in the same increments as the CB channel spacing to 29,405 MHz. That's just two MHz above the 11 meter channel frequencies . . . and that change makes a lot of sense. If you start much lower, you run into the higher powered sideband stations in the lower 350 kHz of the phone band.

Give a call on 28,965 on Sundays at 1000 PDT and you'll probably get an answer from the bunch out in L.A. on the channel . . . if the band is open.

MORE ARTICLES

Perhaps you'd like to see more microcomputer articles in *73* . . . well, write 'em. In *Kilobaud*, I am exploring the advantages of getting into this new field and how to do it in my editorials . . . but you can't do much in microcomputing if you don't know anything about microcomputers. Let's see a lot more articles on microcomputing for *73* . . . and it doesn't hurt to bring ham applications into the act.

MARY PLEADS WITH YOU!

A few readers, despite every effort to make reader service simple, have been screwing things up. The worst complaint from Mary, the lovely gal who handles our reader service, is that there are dozens of readers who are *not* sending in their cards. Yes, I know this is difficult to believe, since you all know how much store advertisers put in getting requests for literature. They put even more store in your buying, of course, so don't let reading literature stop you from buying.

The other gripe is that a few readers are making a mess of the card with crosses and blotches. Mary says to circle the number, not obliterate it . . . puleeze! Mary also requests that you sign your name and address clearly . . . and if you're not sure, please ask someone.

THAT AUGUST QST!

If you are in the Maryland, D.C., Northern Virginia, Western Pennsylvania, or Western New York areas, be sure you don't miss getting your August subscription copy of *QST*. That's your August subscription copy, not one from a store . . . don't miss it.

Eye On the Weather?

-- following weather satellites

Interest in the geosynchronous weather satellites is increasing rapidly. Many fine articles have appeared on the construction of receivers, converters and displays. Plotting charts are available for the low orbit satellites. But very little information is available on locating the geosynchronous satellites. This article presents a method of calculating the azimuth and elevation angles needed to point your antenna and, also, an alternate graphical technique.

To aim your antenna, you need the following information:

1. Your latitude and longitude.
2. The longitude of the satellite subpoint.

The result of the computations will be the desired elevation and azimuth. Elevation is the number of degrees the antenna must be tilted above the horizon. Azimuth is the bearing angle the antenna should be turned from true north.

Let us first calculate the azimuth angle. To do this, construct a great circle route which passes through your location and the satellite subpoint. The latitude of all geosynchronous satellites is zero degrees. This great circle is used to determine, first, the distance from the satellite subpoint to your location and, then, the desired azimuth angle. Fig. 1 shows the navigation triangle from which the distance to the subpoint, D, and the azimuth angle, A, is determined. From Bowditch[1] we find that:

$$\mathrm{Hav}\,D = \mathrm{Hav}(|LO1-LO2|)\cos(L1)\cos(L2) + \mathrm{Hav}(|L1-L2|)$$

Where:
Hav D is ½[1-cos(D)];
L1 is your latitude;
L2 is the subpoint latitude (zero);
LO1 is your longitude, degrees west; and
LO2 is the subpoint longitude, degrees west.

This equation was developed for navigation using Napier's Laws for spherical triangles and, hence, is strange in appearance. However, making the necessary substitutions we find:

$$\cos(D) = \cos(L1)\cos(LO1-LO2)$$

From this, it is easy to find D. D is expressed in degrees. Having found D we can now determine A, the azimuth angle, by: Hav A = sec(L1) csc(D) [Hav(90° - L2) - Hav(|D - 90° + L1|)].

This equation can be simplified for geosynchronous satellites to:

$$\cos(A) = 1 - \frac{\sin(L1 + D)}{\cos(L1)\sin(D)}$$

If the subpoint longitude is less than your longitude, the azimuth angle is A. If the subpoint longitude is greater than your longitude, subtract A from 360° to obtain the azimuth angle.

If you are still with me, the elevation angle is calculated next. A drawing of the great circle path is laid out in Fig. 2. The desired elevation angle is labeled B. Here we have a triangle with two known sides, and the angle between them is known. One side is equal to the Earth's radius, 3,440 miles. The other side is equal to the sum of the Earth's radius and the satellite's altitude, 22,300 miles. Using the law of cosines:

$$B = 90^\circ - D - \arctan\left(\frac{3440\sin(D)}{25740 - 3440\cos(D)}\right)$$

Let's examine some hypothetical cases of a station at 37° N. latitude and 76° W. longitude, desiring to receive ATS-1 at 149° W. longitude and ATS-3 at 70° W. longitude.

ATS-1:

$$\cos(D) = \cos(37^\circ)\cos(-73^\circ) = .798 \times .292 = .233$$

$$D = 76.5^\circ$$

$$\cos(A) = 1 - \frac{\sin(113.5^\circ)}{\cos(37^\circ)\sin(D)} = 1 - \frac{.917}{.798 \times .972} = -.182$$

$$A = 100.5^\circ$$

But ATS-1's longitude is larger than the station's longitude, so:

$$\text{Azimuth angle} = 360^\circ - 100.5^\circ = 259.5^\circ$$

$$B = 90^\circ - 76.5^\circ - \arctan\left(\frac{3440\sin(76.5^\circ)}{25740 - 3440\cos(76.5^\circ)}\right)$$

$$B = 90^\circ - 76.5^\circ -$$

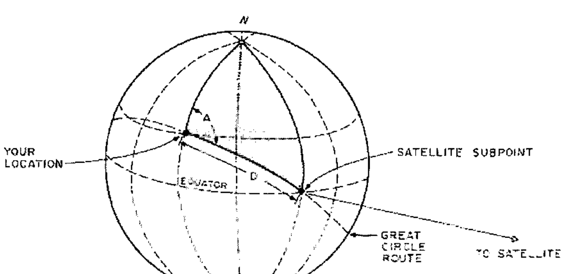

Fig. 1. Navigation triangle formed by your location, the North Pole, and the satellite subpoint.

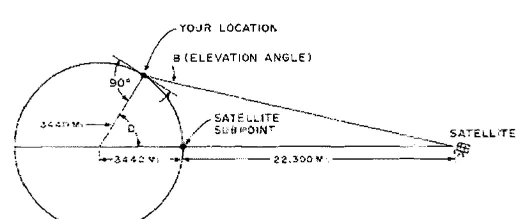

Fig. 2. Geometry used for calculating the elevation angle.

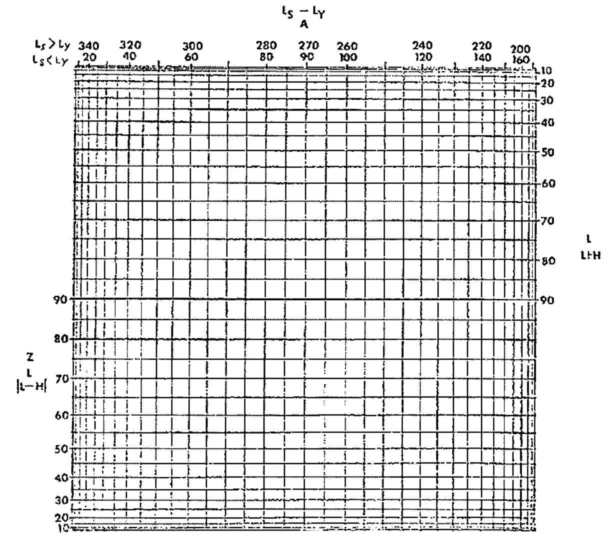

Fig. 3. Simplified d'Ocagne chart. All scales are expressed in degrees. L_S = satellite subpoint longitude; L_Y = your longitude; A = azimuth angle; Z = zenith angle; L = your latitude; and H = 90° - Z.

$$\arctan\left(\frac{3440 \times .972}{25740 - 3440 \times .233}\right) =$$

90° - 76.5° - 7.6°

Elevation angle = 5.9°

ATS-3:

cos(D) =

cos (37°) cos(6°) =

.798 x .994 =

.793

D = 37.5°

cos(A) =

$$1 - \frac{\sin(74.5°)}{\cos(37°)\sin(37.5°)} =$$

$$1 - \frac{.963}{.798 \times .609} = -.982$$

Azimuth angle = 168°

B = 90° -37.5° -

$$\arctan\left(\frac{3440 \sin(37.5°)}{25740 - 3440\cos(37.5°)}\right)$$

B = 90° -37.5° -

$$\arctan\left(\frac{3440 \times .609}{25740 - 3440 \times .793}\right) =$$

90° - 37.5° - 5.2°

Elevation angle = 47.3°

While the mathematical approach is precise and accurate, a much simpler graphical technique can be used with little loss in accuracy. Fig. 3 is a simplified d'Ocagne diagram from Bowditch, which can be used to solve spherical triangle problems by drawing straight lines and doing simple subtraction and addition. Each axis has been divided according to the haversine of the angles. The scales in Fig. 3 are simplified to reduce confusion. The graph applies only to stations in the Northern Hemisphere.

The use of the graph is best explained with examples. Taking the same examples as before, ATS-1 and ATS-3, let us proceed.

Step 1: Mark your latitude on both the left and right vertical scales. Connect the two marks with a straight line.

Step 2: Subtract your longitude from the satellite subpoint longitude, L_S - L_Y. If the result is positive, proceed to step 3. If the result is negative, add 360° to the result to get a positive angle between 0° and 360°. If $|L_S - L_Y|$ is greater than 90°, the satellite is below your horizon and cannot be received.

Step 3: Take the result of step 2 and make a mark on the top axis. Drop a vertical line from this point to the line drawn in step 1. From where the two lines cross, draw a horizontal line to the left scale and note the reading, Z. This value of Z can be converted to the elevation angle B by Table 1. If Z is greater than 80°, the satellite is below your horizon and cannot be received.

Step 4: Subtract the value Z from 90°. The result is labeled H for convenience.

Step 5: Subtract H from your latitude. Ignore the sign of the result. Mark the result on the left vertical scale. Similarly, add H to your latitude, and mark the right scale accordingly. Connect the two marks with a straight line.

Step 6: Where the line from step 5 crosses the 90° horizontal line, extend a line vertically to the top scale. If the satellite subpoint longitude is greater than your longitude, use the upper scale. If not, read the lower scale. The reading is the desired azimuth angle. The elevation angle was obtained from Table 1 in step 3.

The worksheets for ATS-1 and ATS-3 (see Figs. 4 and 5) demonstrate that the errors are typically less than one degree. I find this graphical method to be much faster and easier on the brain than the exact mathematical method, and the errors are much less than the beamwidth of practical antennas.

Aligning the actual antenna mount, in order to use this data, can be difficult. There are two methods I find useful to calibrate the azimuth scale. The elevation scale is easily aligned using a spirit level.

The first, and simplest, method is to use the North Star, Polaris. Rigging a sight on the mount and bore sighting the mount with Polaris at night will bring the mount to an azimuth angle of 0° ± ½°. However, every time I have attempted to use this method I have found a tree, house, or even a mountain between me and Polaris.

The alternate technique requires a copy of the *Nautical Almanac* and the ability to see the noon position of the sun. A *Nautical Almanac* can be purchased at most marine outlets, or a copy is usually available at a local library. When you open the almanac, it appears to be a vast array of tables. Each page pair covers three days. The column we are interested in is labeled "Sun." Under this heading are two subheadings, "Dec." and "GHA". "Dec." is an abbreviation for declination, which is not of importance for our work. GHA is an abbreviation for Greenwich Hour Angle. GHA is the longitude of the solar subpoint. "Dec." is the latitude of the solar subpoint.

Assuming you are in the continental United States, when the sun's GHA is equal to your latitude, the sun is directly south, or at your 180° azimuth position. To the right of the GHA column is a GMT column. To use the almanac, look down the GHA column for the date of interest until you find a GHA near or equal to your longitude. If the GHA matches your longitude, the corresponding GMT is the time when the sun is directly south of your location. If not, you must interpolate. Note that a difference of one hour in GMT corresponds to a change

Table 1. Antenna elevation angles for Z values from 0° to 80°.

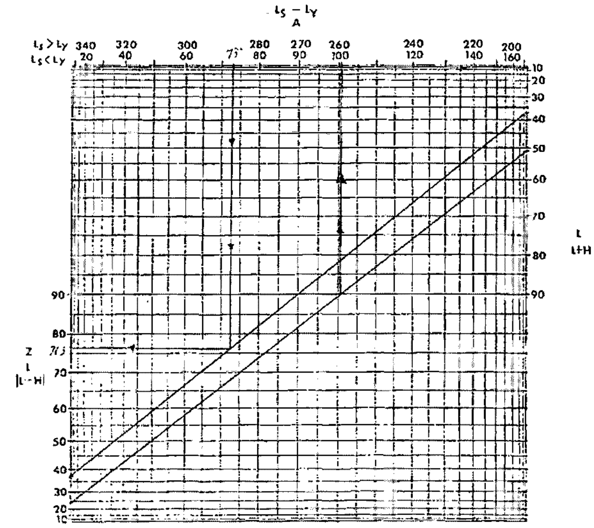

Fig. 4. ATS-1 worksheet. QTH is 37° N., 76° W. Satellite is 0° N., 149° W. L = 37°; L_S - L_Y = 149° - 76° = 73°; Z ≈ 76.5°; H = 90° - Z = 13.5°; |L - H| = 24°; L + H = 51°; A ≈ 259° (259.5° calculated); B (from table) = 5.9° (5.9° calculated).

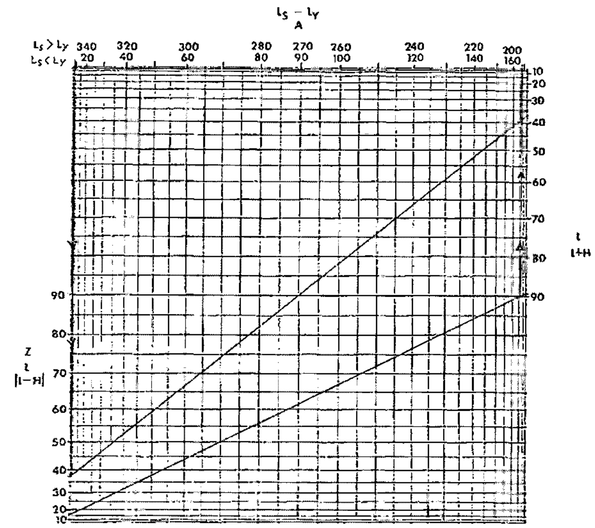

Fig. 5. ATS-3 worksheet. QTH is 37° N., 76° W. Satellite is 0° N., 70° W. L = 37°; L_S - L_Y = 70° - 76° = -6° = 354°; Z ≈ 37.5°; H = 90° - Z = 52.5°; |L - H| = 15.5°; L + H = 89.5°; A ≈ 167° (168° calculated); B (from table) = 47.5° (47.4° calculated).

of 15° in GHA. Taking the largest GHA less than your longitude, note the GMT. Subtract the GHA from your longitude. Divide this difference by 15°, and multiply the result by 60 minutes (time, not angle). This product is the number of minutes which must be added to the noted GMT to obtain the exact time when the sun will be due south. Fasten a stick on your antenna mount parallel to the antenna axis. When the calculated time arrives, point the stick at the sun by watching the stick's shadow (never look directly at the sun). Your azimuth scale can now be set to 180°. By the way, an error of one minute in time is an error of only ¼° in azimuth. ■

Social Events

CLEARWATER BEACH FL
NOV 19-20

The Florida Gulf Coast Amateur Radio Council is holding its 2nd annual convention on November 19 and 20, 1977 at the Sheraton Sand Key Hotel on Clearwater Beach FL. Official attendance at our last affair was placed in excess of 2200, and this year we expect to double that number as we increase the number of activities and size of the convention. For more information contact: Florida Gulf Coast Amateur Radio Council Inc., PO Box 157, Clearwater FL 33517.

MASSILLON OH
NOV 20

The Massillon ARC 16th Annual Hamfest and Auction will be held Sunday, November 20, 1977, at a new location: Towne Plaza Shopping Center in downtown Massillon, Ohio. Unlimited parking. Major prizes given away. Starts 9 am – admission $1.50 at door. Mobile check-in 146.52 simplex. For brochure and map write to MARC, PO Box 73, Massillon OH 44646.

ELLICOTT CITY MD
NOV 27

The Columbia Amateur Radio Association (CARA) will hold its CARA Hamfest on November 27, 1977, at the Ellicott City Armory in Ellicott City, Maryland. Program includes exhibits, flea market, prizes, and refreshments. All indoors. No tailgating. Talk-in on 147.99/39, 146.16/76, 146.52/52. For more info contact CARA, PO Box 850, Columbia MD 21044.

OAK PARK MI
NOV 27

The Oak Park High School Electronics Club is presenting a Swap and Shop on Thanksgiving Sunday, November 27, 1977, at Oak Park High School, Oak Park, Michigan 48237. Refreshments and door prizes. Donation, $1.00. Table, $1.00.

FORT WAYNE IN
JAN 22

The annual Fort Wayne Winter Hamfest will be held on January 22 at Shiloh Hall, north of Fort Wayne, from 8 am until 4 pm local time. Early parking is available and 28/88 and 52/52 will be monitored. This yearly event is sponsored by the Allen County Amateur Radio Technical Society (AC/ARTS). Admission is $2.00 at the door. Table space is available at $1.50 per half table (about 4 feet).

New Products

from page 168

the vehicle dash panel with the microwave horn "peeping" through the windshield. The power plug simply plugs into the cigarette lighter. It is designed to operate from the 12 volt battery with either positive or negative ground with low power consumption. The electronics is housed in a handsome 5-1/4" x 4" x 3-1/8" high steel cabinet with a black textured finish.

The operator controls are intentionally limited to a single three-position switch with the following functions: 1) system test; 2) radar detection, visual indication only; 3) radar detection, simultaneous audio and visual alarm. The Bird Dog has thus been designed to eliminate the troublesome, and usually unsatisfactory, gain adjustment control knob found on competitive units. The elimination of this gain adjustment also enhances the unit for out-of-sight mounting if the user so desires, such as under the hood with the microwave horn "peeping" through the grille opening.

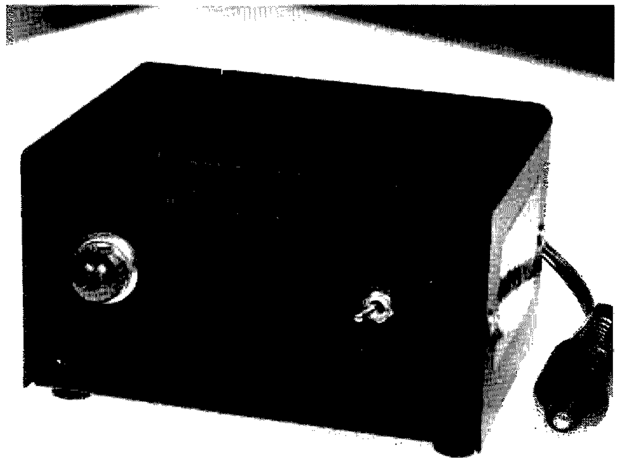
The unit features a high gain, die-cast, aluminum microwave horn and rf cavity tuned to 10.525 GHz. A pair of microwave diodes are located in the cavity, one for modulation of the continuous rf carrier and the other for detection of the low-level radar signal.

The detector diode drives a low noise, low level, metal package, linear integrated circuit amplifier. The low noise and metal package along with other appropriate filtering and shielding virtually eliminate false triggering from spurious sources. The output circuit consists of a phase locked loop integrated circuit package whose bandwidth is controlled to ±5% of the local oscillator to virtually eliminate any unwanted frequencies beyond the range of the phase locked loop's local oscillator. The output driver drives both an audible buzzer and a red jeweled indicator light.

The kit assembly is simple and no special training is required. The kit can be completely assembled in one evening.

The Bird Dog kit, including a set of detailed plans for construction, sells for $49.95, or, if you prefer, $74.95 for a preassembled and fully tested unit, plus $2.00 for postage and handling. A set of detailed construction plans can be purchased separately for $5.95 and is discounted from your purchase price when you purchase a Bird Dog kit.

The Bird Dog is available through *Micro Electronics, 1921 I-85 South, Charlotte NC 28208, telephone (704) 392-1705.*



The Bird Dog.

NEW AND IMPROVED ELECTRONIC KEYER FROM HAM RADIO CENTER

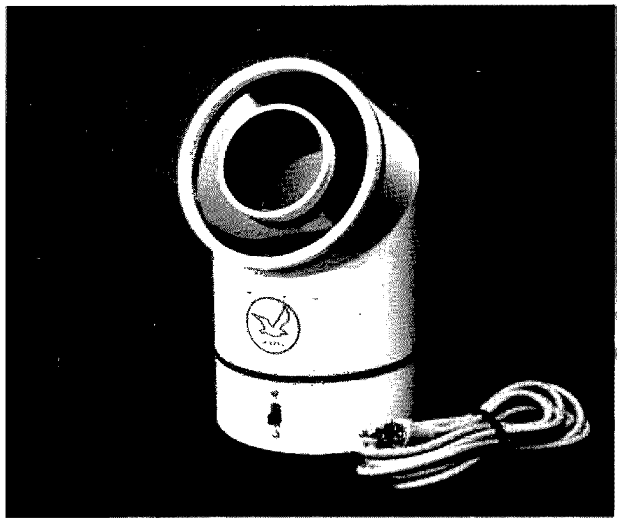
Years of experience in the manufacturing of amateur radio equipment (the famous Ham Keys) are what is behind Ham Radio Center's new and improved electronic keyer . . . Model HK-5A.

Outside, it features a trimmer cabinet color-keyed to match most modern amateur radio equipment, with all front-mounted controls (speed, weight, tone, and volume) and jacks for external paddle and/or keyer, plus external power. Inside, this battery-operated unit has an iambic circuit for squeeze keying, self-completing dots and dashes, a dot memory, built-in tone monitor and grid block, and direct keying. Batteries *not* included. Also, it can be used as a code practice oscillator with a straight key.

For more information about Model HK-5A, write *Ham Radio Center, Inc., 8340-42 Olive Boulevard, P.O. Box 28271, St. Louis MO 63132,* or call (toll free) 1-800-325-3636.

CW SPEAKER SYSTEM USES ACOUSTIC FILTER

Skytec of Ukiah, California, is offering a loudspeaker unit designed expressly for CW. Employing a unique acoustic chamber resonator, the Skytec CW-1 combines good "single frequency" selectivity with a nice tone shaping characteristic.



The Skytech CW-1.

By filtering right at the audio output to the room, the unit suppresses hum, hiss, ringing, and miscellaneous noises left in the audio by most receivers. The CW-1 adds a remarkable degree of selectivity to receivers without a sharp electronic filter, and it gives the best of receivers the most pleasant, "just right" tone output and bandpass for long QSOs, net operating, and band scanning, Skytec says.

Priced at $19.95, the 3½" by 6½", 2-pound unit is shipped with a connecting cable. A front switch provides for bypassing the audio to the regular station speaker for other than CW reception. *Skytec, Box 535, Talmage CA 95481.*

The Model HK-5A keyer.

from page 6

CB IN PERSPECTIVE

While a lot of amateurs are still uptight over CBers and their often wanton ways, others are busy welcoming the cream of the CB crop into amateur radio. About 80% of the new hams are coming from the CB ranks, a heavy percentage of those being the highly illegal HFers. Oddly enough, despite all sorts of warnings of disaster, the new hams are doing quite well.

But what about the manufacturers? We are now seeing more and more of the CB firms turning to amateur radio . . . how come? In this case we can laugh, for the CB industry went to a lot of expense and trouble to almost mortally wound itself.

Back in the glorious days when everything was back-ordered and the manufacturers were more worried about completion of construction of their new plants than anything else, the bigwigs of the biz did invest some money toward making their future even rosier than it then appeared. They could see the 23 channels then available rapidly filling up and there being not only a need for more channels on 27 MHz, but also a need for two to five megahertz for further CB development, as millions of people got into the act.

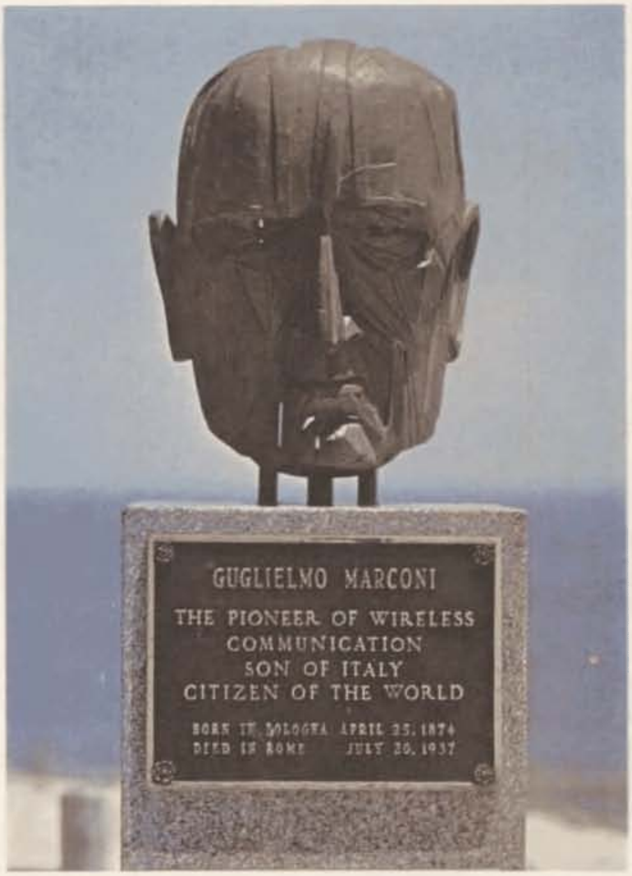
The "donations" went to their lobby in Washington. Here the money was spent to put the pressure on the FCC for new bands and for 27 MHz expansion. When they ran into resistance from the FCC, they then went via the OTP (White House) to force the FCC to capitulate. It's actually a bit more sordid than that, but you get the idea.

Through TV, movies, records, and a lot of newspaper and magazine publicity, the pressure was kept on to keep CB growing . . . and it did. Then the plan to expand the 27 MHz band went through the usual FCC heel dragging, which amateurs are all too familiar with, and suddenly the country was faced with the choice of buying a CB set which would be virtually worthless in six months or else waiting six months for the new 40-channel sets. Sales of CB sets just about stopped, while the factories in Japan kept grinding out the 23-channel sets to further bulge already-bulging warehouses in the U.S.

By the time the 40-channel sets could be purchased, the steam had gone out of the market and the demand for the new sets never really materialized. That lesson having been learned, the pressures for opening a new CB in the VHF or UHF bands cooled quickly. Of course, the lack of pressure has not stopped the FCC from its considerations in this line . . . these things move like a glacier and are as difficult to stop. One of the last things CB manufacturers and dealers need now is a new Citizens Band.

One publisher, anxious to start a new "Communicator" magazine, did manage to pull the FCC to a halt by writing in a nationally-syndicated CB column that the new band would soon be announced. The FCC took this as a challenge and tabled the whole matter. They are not about to be pressured like that.

My plan to encourage ham clubs to institute Novice classes has worked well, and the result has been a substantial growth in amateurs . . . enough so the need for a Communicator class of license is no longer important. The two reasons for the Communicator proposal were to pro-



Memorial bust of Marconi at the station site.

The listed data tells you the time and place OSCAR crosses the equator in an ascending orbit for the first time each day. To calculate successive orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the first crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world, it will descend over you. To find the equatorial descending longitude, subtract 166 degrees from the ascending longitude. To find the time it passes the north pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR when it is within 45 degrees of you. The easiest way to do this is to take a globe and draw a circle with a radius of 2480 miles (4000 kilometers) from the home QTH. If it passes right overhead, you should be able to hear it for about 24 minutes total. OSCAR will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15 degrees from you, add another minute; at 30 degrees, three minutes; at 45 degrees, ten minutes.

OSCAR 6: Input 145.90-146.00 MHz; Output 29.45-29.55 MHz; Telemetry beacon at 29.45 MHz.

OSCAR 7 Mode A: Input 145.85-145.95 MHz; Output 29.40-29.50 MHz.

Mode B: Input 432.125-432.175 MHz; Output 145.925-145.975 MHz.

Orbits designated "X" are closed to general use. "ED" are for educational use. "BTN" orbits contain news bulletins. "Q" orbits have a ten Watt erp limit. "L" indicates link orbit. "N" or "S" indicates that Oscar 6 is available *only* on northbound or southbound passes. Satellites are not available to users on "NA" days.

LETTERS

W6LS

I have not seen a Caveat Emptor section in *73 Magazine* for a long time. If you no longer print ads, ignore the two typed below. However, if you still conduct this service, please print the following ads:

CQ and QST 1950-1975 issues for sale. Send SASE if ordering 73, Ham Radio, *or other CQ and QST issues. One dollar minimum order, and all issues cost 25¢ each, including USA shipping. Send chronological list and full payment to W6LS, 2814 Empire, Burbank CA 91504.*

Certificate for proven two-way radio contacts with amateurs in all ten USA call areas. Award suitable to frame, and proven achievements added on request. SASE brings TAD data sheet from W6LS, 2814 Empire, Burbank CA 91504.

As you may remember, our club has operated a used amateur radio magazines service for more than a decade. It was your donation of *73 Magazines* that enabled us to start this project. We have shipped more than 3000 issues in one month, and we seldom send less than 300 magazines during a month. Our magazine service is appreciated by amateurs, and we have filled requests from every state and about 40 countries. We often receive very kind comments from amateurs who are happy to receive needed issues. Our club is a nonprofit organization, and we regularly donate "income" to worthwhile causes associated with the amateur radio service. As is indicated in our ad, our supplies of *73* and *Ham Radio* issues are always limited, and we have actually been completely out of them several times in the last few years.

We hope you understand that you and your staff are welcome to drop in at W6LS for unannounced visits whenever you are in our area. We are open weekday evenings 4:30-5:30 pm and 7:30-9:30 pm. Actually, W6LS is open and active at least 30 hours per week. Please extend our invitation to your staff. We are pleased to see Bill Pasternak whenever he attends an event at W6LS, and that is usually a couple of times per year.

W6LS is still as active as ever. We help license about 300 amateurs per year in the courses our members teach, including about 150 at W6LS. We actively support amateur-related activities, such as communications for Walk-A-Thons and Bike-A-Thons. We have hosted repeater conferences the last few years, along with meetings of other special interest groups such as SOWP, QCWA, OOTC, Ten-Ten International, Southern California Antique Radio Society, Southern California Radio Teletype, MARS groups, and others. We continue to be active in community affairs, such as through our hosting of the annual volunteers recognition day (Sunday, 25 September 1977) for the Burbank Red Cross. W6LS is also collecting donations of aluminum in 1977, and spending the income to buy refreshments for Red Cross blood donors in Burbank. Our 12th annual convention drew a little more than 3000 attendees, and we have reached the point where we are considering a move to larger quarters. W6LS has served as the receiving point for the ARRL California Incoming DX QSL Bureau during the last few years, and it runs smoothly now with plenty of help. W6LS sorts received SASEs and DX cards according to the first letter in the callsign suffix, and we ship packages to individual suffix sorters, who are members of other clubs in our Los Angeles Area Council of Amateur Radio Clubs. We are so deeply involved in several major projects that our clubroom looks like a combination storage room and junk shop.

I have taken up Herb Brier's (W9AD) old battle to help new amateurs through the Novice column in *CQ Magazine*. As you may recall, I have a lot of interest in the problems faced by new amateurs in general and Novices in particular. I hope to provide them with some help via this column, although I realize it may not last long (since the FCC is making noises about eliminating the Novice class of license).

I established an amateur radio operating award to provide a bit more incentive to new amateurs and to honor our beagle dog (Tad) who spent more time at W6LS than most members while he was alive. The Ten American Districts certificate is increasingly popular with new amateurs, and I have already issued almost 1200 of them to amateurs in all states and about 50 countries.

William Walsh W6DDB
LERC Amateur Radio Club/W6LS
Burbank CA

Hi, Bill . . . congratulations on the column in CQ . . . and sorry we are out of the classified business these days. We'll try to be sure to say hello on our next trip out your way . . . keep up the good work with Novice classes. — Ed.

HOT TICKET

I'm an air conditioning engineer who's worked the past year in Iran, where it's been 102° F. for the past month. I've been a ham for about seven years, and have had callsigns OD5GT and FØAZK. I now operate here in Tehran with callsign EP2GT. We also have a radio club here with about 60 members. Some of these members receive *73* by air mail from their American companies, so I've been able to keep up a bit on ham radio activities through your fine publication.

Bill Schlapfer EP2GT
Tehran, Iran

BRAVO

Bravo for your October editorial, "Can The QCWA Save Amateur Radio?"

I am in accordance with you 100% — this fine organization, above any other, could do the job that ham radio sadly needs.

I, regretfully, am not a member, but am joining as soon as possible. Having been in ham radio about 50 years, I guess I'm about due.

I understand that such an illustrious gentleman as Leo Meyerson has recently been elected as a regional director. Along with many good men in just about every walk of life, who do not seek monetary gain and show no discrimination toward old or new, who else should represent us except (as I have mentioned previously) Wayne Green? . . .

Paddy Labato W8DLU
Cleveland OH

REAL PROBLEMS

Regarding the recent announcement of the Rule and Order on FCC docket #21033: I would like you to consider supporting an addition to this controversial issue (at least in the midwest).

As I am not a Tech, I feel that I am less biased on the subject than most Techs are — but I still feel strongly that the potential problems need immediate consideration and action.

I am very disturbed by the talk in the weak signal portions of our VHF bands of a so-called "war." Now, as in many times in the past, is the time for cooperation between all concerned, not "war." Quoting a recently overheard comment on 145.1 MHz, "I'll throw my kW on the first repeater input down here." War is a two-way affair, and FMs have kWs also.

In general, FMers and low band operators whom I have discussed this with realize that DXing, EME, RTTY, TV and satellites use some of the VHF spectrum, but they don't know how much or where. They have been very receptive and sympathetic to our potential problems, and would support gentlemen's agreements and/or proposals to the FCC to prevent the potential problems.

My personal feeling is that the Rule and Order makes sense, except that it did not go far enough. Gentlemen's agreements can solve the problems of 220 MHz and up if they are made known and are respected by all parties concerned with the use of these bands. Two meters, as I see it, is where the problem lies. No good argument can be made that FM users and repeater operators didn't need the extra 1 MHz given on 2 — the problem is going to be that the 300 kHz that are usable by the Tech class for AM, SSB, CW, TV, RTTY, facsimile, and EME from 145.5 to 145.8 MHz is not going to be enough. General class license holders and above do far more work in the area above 145.0 MHz at present than in the 144 MHz portion, due to the tremendous activity generated by the Tech class. You go where the action is.

As I see it, the only answer is to open up the lower portion of 2 meters to Techs. The 500 kHz from 144 to 144.5 are probably adequate, when combined with the 300 kHz from 145.5 to 145.8, to handle all modes and uses. The bottom 100 or 50 kHz could and probably should be reserved for A1 only.

If the bottom of 2 is not opened to the Techs, I foresee some real problems for all users of the band.

Jerry G. Shepherd WB9YPW
Hoffman Est IL

EARNING

I just finished reading the letter from Mark A. Clark WB4CSK in the September *73*. He may be "just a kid," but he has the attitude of a mature adult and I agree with his feelings 100%. There is no excuse for lowering ticket requirements to gain strength in numbers.

I am working toward my Novice now, and I want the satisfaction of *earning* it. I'm a CBer, somewhat disappointed with CB, and it's my observation that if 90% of the CB operators knew more than how to key the mike and talk, we would have much less trouble with RFI, overmodulation, splatter, and crude manners.

Amateur radio doesn't need this kind of membership.

Dave Dunsmoor KAHB1022
Wahpeton ND

PACING

I have recently become a subscriber to your magazine, after belonging to the ARRL for more years than I care to remember.

I enclose a letter which I wrote to *QST* and which was returned to me with a copy of an old *American Medical Journal* article which merely stated the well-known facts that some later pacemakers have better shielding than some earlier models.

I had hoped that my experience might at least stay on file for the benefit of others who have the problem. Since receiving my letter back, I have withdrawn my permission for *QST* to use my experiences.

Perhaps I had better say that when

Gonzales CA 93926

In this installment, we'll leisurely play around with Ohm's Law and tie up some loose ends from Part 1.

First, to Ohm's Law. Probably the simplest statement is: voltage = current x resistance. In symbols, E = IR (remember, it's not necessary to put a multiplication sign between letters). And what it means is that the instantaneous voltage or pressure across a purely resistant circuit equals the amount of current flowing times the resistance offered to that flow. I used the words "instantaneous" and "purely resistant" to take care of ac as well as dc circuitry. The further you get into electronics, the more you see of such bothersome little distinctions. Things are just never simple!

Let's now do some algebraic wiggling like we did in Part 1. If E = IR (back to playing with number equations if necessary), then I = E/R and R = E/I. Which is to say that the current in a purely resistive circuit equals the voltage (pressure) divided by the resistance (the greater the voltage and the less the resistance, the more the current, just like a hose carrying water), and the resistance in the circuit equals the voltage divided by the current (the greater the voltage and the less the current, the greater the resistance must be).

Now an example: Suppose you wanted to develop 5 volts across a resistor that carried 25 milliamps (mA) of current. What size resistor would you need? Here we're looking for the R of our formula. A good way to remember the Ohm's Law formulas is simply to note that E, voltage, is always on top, never on the bottom of the fraction. R = E/I, then, is the form we want here. But there's a problem. The formula works for Ohms, volts and Amps (Amperes), whereas here we have *milliamps*. Using the proper units is always a critical factor in these problems, as it is in any measurement situation. You might be 6 feet tall. You most certainly are not 6 inches tall. The number (6 in this case) means nothing unless it's hooked up with the correct unit of measurement. So in our problem milliamps are no good if we want our answer in Ohms (but, as we shall see, they are fine if we want our answer in kilohms).

But this again brings up the subject of prefixes, which is quite a subject indeed. Milli and kilo (and the mega we saw in our last lesson) are examples. They are hooked onto the front of a unit word and completely change the size of that unit. Milli, for example, means thousan*dths*, kilo means thousan*ds*, mega means millions. So 25 mA is 25 thousandths of an Amp (0.025 A). Notice how much shorter the phrase *25 milliamps* is than the phrase *25 thousandths of an Amp*. Also note that with 0.025 you're into decimals, whereas with 25 you are not. Learning to work with prefixes, abbreviations and other shortcuts is mighty important in electronics computations, unless you don't mind taking up lots of space and time in computations that could be done with dispatch.

But to finish our problems, we now know that 25 milliamps is 0.025 Amps, something that we can plug into our formula even if we have not yet learned shortcut ways of handling decimals. R = E/I becomes R = 5/0.025 for our problem. Dividing bottom into top, we get 200. So 200 Ohms is the resistance we want.

Let's check our work. To do so, we'll again use Ohm's Law, but the configuration E = IR. If we've done our work correctly, 5 volts should equal 25 mA times 200 Ohms. Multiply 0.025 x 200 and, sure enough, up comes 5. We must have done things the right way.

Before we jump back into prefixes and decimals to tie things together for this installment of our series, let's take further note of units of measurement, since, as we've already seen, keeping these units straight in our work is pretty important. Notice how we multiplied Amps and Ohms together to get volts! Wow, all different units! That often happens with multiplication and division. The units of measurement of the answer may be entirely different from those of the problem. That's not true of addition and subtraction. If I add so many Ohms plus so many Ohms, I'll get Ohms in my answer. If I subtract so many volts from so many volts, I'll get volts in my answer. The reason you get different units with division and multiplication is that units cancel just like numbers cancel: $\cancel{5} \times 7/\cancel{5} \times 9 = 7/9$. The fives cancel. Or else one unit of measurement is defined in terms of other units so that they can be interchanged with those other units and you're still dealing with the same reality. The thing to remember is that units are handled *logically* in computations. With addition and subtraction, you'll get the same units in the answer as you had in the problem. With multiplication and division, you'll drop some units or get new units, but the units you dropped were canceled out and the new units were just "hidden" in the original units because of the *definition* of those original units. An example: Drive a car at 55 miles per hour for 3 hours and you've gone 165 miles. What happened to the hours? Here's what happened: 55 miles/hour x 3 hours = 165 miles hours/hour. The hours canceled because they were in top and bottom. Note also that when you say *per*, you mean divide. 55 miles per hour means 55 miles/1 hour. That may seem strange, but it all works out very nice and logically.

Another example. 7 miles equals 36,960 feet. How's that? Miles and feet are totally different units! Here's what you didn't see. There are 5,280 feet *per* mile. So we have 7 miles times 5,280 feet/1 mile. The miles cancel and we get 36,960 feet. That kind of thing goes on all the time in electronics. You just take the disappearance and reappearance of units for granted when a multiplication or division is involved.

Now some decimal stuff. There's just no way of avoiding it, though we have skirted around it so far. Perhaps 99% of computations in electronics require good working knowledge of our decimal system.

A decimal system is a *ten* system (from the Latin *decem*, meaning ten). Every time you move to the left, you multiply by ten; every time you move to the right, you divide by ten. In the number 777.7, the left-hand 7 is ten times bigger than the 7 to its right. That one, in turn, is ten times bigger than the one to its right, and so on. 777.7 means 7 hundreds + 7 tens + 7 ones +7 tenths, 700 + 70 + 7 + 7/10.

Naming numbers in our decimal system can be kind of tricky, because there's a variety of ways, all meaning the same thing. 7,700 can be named seven thousand seven hundred, or seventy-seven hundred. 0.025 is normally named 25 thousandths, though it means 2 hundredths and 5 thousandths. Look at the fraction equivalent, and you can see why. 2/100 + 5/1000 = 20/1000 + 5/1000 = 25/1000. Normally numbers smaller than one are named by the last digit to the right. 0.7 (by the way, a zero is usually stuck in before the decimal point just to make sure everyone understands it *is* a decimal point we are dealing with and not a period or something, and that there are no other digits to the left of the decimal) is seven tenths, because the 7 is in the tenths column. 0.93250 is nine-thousand three-hundred and twenty-five ten-thousandths, because the 5 is in the ten-thousandths column (you don't consider zeros to the right of that last non-zero digit, 5 in this case). 0.035 is thirty-five thousandths because the 5 is in the thousandths column. Using prefixes: 325 milliamps (remember, milli means thousandths) is 0.325 A. The 5 goes in the thousandths column because it is the digit to the right. 37 kilohms (remember, kilo means thousands) is 37,000. The 7 is the digit to the right and so goes into the thousands column. You'll notice I snuck one in there. 37 kilohms is not smaller than one! Prefixed numbers follow the rule whether larger or smaller than one.

Fig. 1 shows an unwieldly number, 86,732,174,626.908761435 (that's 86 billion, etc.), with the names of each column written above, just in case you're not familiar with those names. If you wish to test your knowledge, you might try translating that monstrous number completely into words. (Check yourself against the note at the end of this piece.)

You will no doubt recall that the rules for adding and subtracting decimals are pretty simple. You just keep the decimal points directly above and below one another. 3.025 volts + 765 volts + 0.00096 volts becomes:

3.025 V
765 V
+ 0.00096 V

You can fill in zeros if you want. And note that 765 has an invisible decimal point to its right. Any number in our system has that invisible point if none is showing, and you have to make it visible when doing computations. So you might do the problem:

003.02500 V
765.00000 V
+ 000.00096 V
768.02596 volts

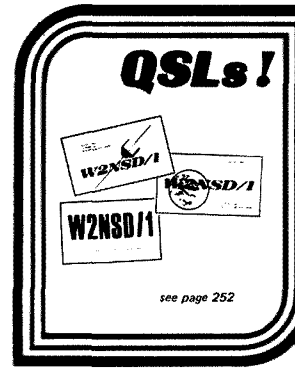
Notice how those decimals are kept in a straight line.

Subtractions are done pretty much as you might expect. 28.966 milliamps - 0.00046 milliamps becomes:

28.96600 mA
- 00.00046 mA
28.96554 milliamps

ten-billions	billions		hundred-millions	ten-millions	millions		hundred-thousands	ten-thousands	thousands		hundreds	tens	ones		tenths	hundredths	thousandths	ten-thousandths	hundred-thousandths	millionths	ten-millionths	hundred-millionths	billionths
8	6	,	7	3	2	,	1	7	4	,	6	2	6	.	9	0	8	7	6	1	4	3	5

Fig. 1.



Abbreviation	Prefix	Size	Examples
p	pico	trillionths	7 pF means 7 picofarads, 0.000000000007 farads
			5 ps means 5 picoseconds, 0.000000000005 seconds
n	nano	billionths	1 ns means 1 nanosecond, 0.000000001 seconds
			3 nF means 3 nanofarads, 0.000000003 farads
μ	micro	millionths	8 μF means 8 microfarads, 0.000008 farads
			9 μs means 9 microseconds, 0.000009 seconds
			6 μV means 6 microvolts, 0.000006 volts
			4 μH means 4 microhenrys, 0.000004 Henrys
m	milli	thousandths	2 mA means 2 milliamps, 0.002 Amps (Amperes)
			5 mV means 5 millivolts, 0.005 volts
			7 mW means 7 milliwatts, 0.007 Watts
			3 mH means 3 millihenrys, 0.003 Henrys
			1 ms means 1 millisecond, 0.001 second
c	centi	hundredths	6 cm means 6 centimeters, 0.06 meters
k	kilo	thousands	9 km means 9 kilometers, 9000 meters
			8 kV means 8 kilovolts, 8000 volts
			4 kW means 4 kilowatts, 4000 Watts
			2 kΩ means 2 kilohms, 2000 Ohms
			3 k$ means 3 kilobucks, $3000!
M	mega	millions	5 MΩ means 5 megohms, 5,000,000 Ohms
			7 MW means 7 megawatts, 7,000,000 Watts
			6 MV means 6 megavolts, 6,000,000 volts

Table 1. Common abbreviations and prefixes.

Note the zeros we threw into both those problems. It's often quite helpful to throw in or take out zeros like that. (Of course, you can't do it in the middle of a number or between the decimal point and some other digits. 706 is not the same as 76. 0.009 is not the same as 0.9. 73,000 is not the same as 73!) Only zeros at the extreme right or left can receive that kind of treatment.

Multiplying decimals is simple enough. Just multiply as though there were no decimal point, then count up the number of decimal places in both the numbers you multiplied and add those two counts. That's how many places are in the answer. Example: 0.000037 Amps x 26,000 Ohms might be done simply:

```
 26,000
   x 37
 182000
 78000
 962000
```

There are no decimal places in 26,000, but there are 6 in 0.000037. So there will be 0 + 6, or 6 places in our answer. It becomes 0.962000, or, dropping those unnecessary zeros to the right, simply 0.962. (Of course, you have to count the 6 places while the zeros are still there.) If that was an Ohm's Law problem, our answer is 0.962 volts.

Decimal division is more difficult. We'll do a couple problems and state the rule at the same time. Problem: 18.73 volts ÷ 6.9 milliamps (remember, that's 0.0069 Amps).

```
0.0069)18.73
```

(1) 00069.
Rule: Move the decimal point of the divisor (the number you are dividing by) all the way to the right.
(2) 69.
Rule: Drop the unnecessary zeros.
(3) 69
Rule: Let the decimal point become invisible.
(4) 187300.
Rule: Move the decimal point of the dividend (the number you are dividing into) the same number of places to the right as you did for the divisor. Add as many zeros to the right as necessary to do this.
(5) 69)187300.
Rule: Put the problem together with these new numbers and set a decimal point for the answer directly above the point in the dividend.

```
        2714.4
(6)  69)187300.0
        138
(7)      493
         483
(8)       100
           69
           310
           276
            340
            276
             64
```

Rule: Paying no further attention to the decimal point, proceed with the division as you would with any other division, putting each digit of the answer above the last digit to the right of the digit or digits you just divided into.

Rule: If necessary to get a decent-sized answer, add zeros to the right of the decimal point in the dividend. (We added one here, even though it was not necessary.)

Rule: If applicable, fill in the space between the decimal point and the first digit to the right with zeros. (This does not apply here, but will in the next problem.)

In the above problem, we stopped dividing after getting one decimal place in our answer. Actually, we could have stopped a lot sooner. Remember (Part I) that you seldom need more than 2- or 3-digit accuracy in electronics. If this was an Ohm's Law problem, an answer of 2700 Ohms would be plenty accurate in most cases.

Let's try another problem, in order to see where the last rule applies: 12.6 volts ÷ 47 kilohms (remember, that's 47,000 Ohms).

```
47,000)12.6
```

(5) 47000)12.6
Rules: Notice that rules 1, 2, 3, and 4 do not apply, since the decimal point is already to the right in 47,000. This brings us to 5, 6 and 7. And note that to apply 6, we first must use rule 7.
(7) 47000)12.600000
Rule: To get 3-digit accuracy, we have to add 5 zeros to the 12.6.

```
(6)               268
     47000)12.600000
             9 4000
             3 20000
             2 82000
               380000
               376000
                 4000
```

Rule: Note where that first digit of the answer goes (above the last digit to the right that you are dividing into that first-step). Very important! Also important: Keep digits directly above or below the correct digits in the subtraction process. That helps avoid errors.
(8) .000268
Rule: If you didn't leave that space for the 3 zeros, your answer would be incorrect.

Our Ohm's Law answer is 0.000268 Amps, which is 0.268 milliamps or 268 microamps.

These divisions can get mighty hairy. That's why next time we'll get into some pretty clever methods for handling divisions and a lot of things that are simply too difficult otherwise.

This brings us finally to abbreviations and prefixes. Look over the Table 1 above rather carefully. There are other abbreviations and prefixes, but these are the common ones. It'll be quite useful to have these stashed away in your mind for future reference.

Now try this exercise. Check yourself against the work and answers at the end of the column.
(1) Solve for the unknown using Ohm's Law:
(a) 750 V, 330 mA, R = ?
(b) 470 Ω, 11 mA, E = ?
(c) 18 V, 2200 Ω, I = ?
(2) In the same way that we did 777.7, break down this number: 17.352.

Note

Answer: Eight-six billion seven hundred thirty-two million one hundred seventy-four thousand six hundred twenty-six *and* nine hundred eight million seven hundred sixty-one thousand four hundred thirty-five billionths!

Work and Answers to Exercises

(1) (a) $R = \frac{750}{.330}$

```
       2,272
330)750,000
    660
     900
     660
     2400
     2310
       900
       660
       240
```

It's best to round answer out to 2300 Ohms.

(b) E = 470 x 0.011

```
 470
 x11
 470
470
5170
```

There are 3 decimal places in 0.011, so the answer is 5.170 or 5.17 volts.

(c) $I = \frac{18}{2200}$

```
       .00818
2200)18.00000
     17 600
        4000
        2200
        18000
        17600
          400
```

Answer: 0.00818 Amps or 8.18 mA.

(2) 1 ten + 7 ones + 3 tenths + 5 hundredths + 2 thousandths, or

$$10 + 7 + \frac{3}{10} + \frac{5}{100} + \frac{2}{1000}$$

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Ham curiosity being what it is, I'm sure any of you with HF receivers have chanced across funny-sounding signals on the low end of 80 or 20. By now, you should be aware that the "tweedle-tweedle-dee" you hear is FSK RTTY. This month we shall investigate, in general terms, methods of decoding transmitted RTTY.

To begin with, recall that there are two methods of transmitting RTTY presently in use: FSK and AFSK. When operating AFSK, you are presented with two audio tones, on standard frequencies (2975 Hz and 2125 Hz), regardless of the rf carrier frequency. FSK, however, presents two rf "tones" which, while their relationship is standard (850 Hz or 170 Hz apart), may be any of an infinite number of discrete frequencies.

Logically, our first task is to convert the FSK into something standardized for decoding – AFSK! *Fig. 1* illustrates how one obtains the proper frequencies. Note that the FSK is tuned much in the manner of lower sideband, but that the bfo frequency is set to reproduce the 2 kHz tones rather than speech. For those of you with crystal bfos (such as the Heathkits), a third bfo rock should be used to provide the appropriate offset.

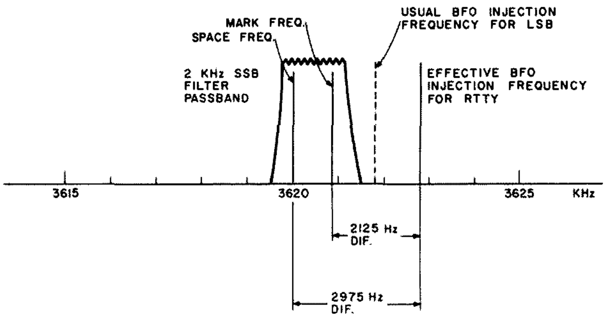


Fig. 1.

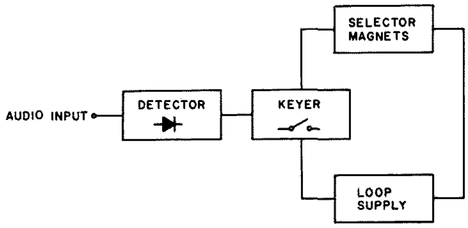

Fig. 2.

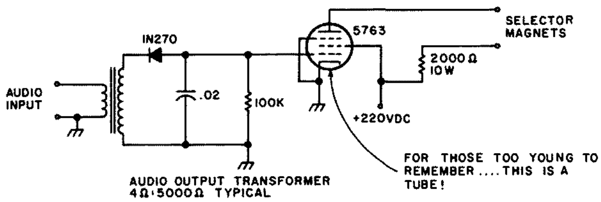

Fig. 3.

By the way, receiving schemes are available which convert not to audio, but to the receiver i-f frequency, typically 455 kHz, and demodulate from there. These systems are analogous to those covered here, but will not be specifically discussed.

So, how do you get the "tweedle-dee" to key your Model 15? Let's take a giant step backward. Remember ON-OFF keying? I told you that would come *in* usefull *Look* at the block diagram in Fig. 2. A tone arriving at the input is "detected," i.e., rectified, and applied to a keying stage. The keying stage is an electronic switch that is closed in the absence of a signal, but opens when such a signal is input. Feeding an ON-OFF keyed space signal into this primitive converter would produce a usable output, or, by keying a relay to invert the signal, on-off mark keying could be used.

Of course, we don't use ON-OFF keying, though, so what can we do? The simplest thing is to tune the HF receiver bfo so that the mark frequency is zero beat. The audio is then an 850 Hz (or 170 Hz) ON-OFF keyed space tone, and can be decoded by the practical circuit shown in Fig. 3. This is one of the circuits constructed and used at WA3AJR during the mid-1960s.

A more advanced approach is to use this basic circuit twice, on both the mark and space signals. By using filters tuned to the appropriate frequencies, each tone may be directed through a detector, and to keyers which would alternate polarity for mark and space. A special relay, called a "polar relay," can be driven off this alternating signal to key the loop. This scheme became known as the "W2PAT" converter, after its daddy, and is block-diagrammed in Fig. 4. With a "combiner" stage added to dispense with the polar relay and key the loop directly, this circuit remains an easy-to-understand way to get into RTTY reception.

Upon this foundation comes a whole raft of demodulator designs. Thoughts and concepts such as limiter vs. limiterless detectors, AM vs. FM techniques, and multiple other refinements have been debated. Additional circuits, such as autostart or character recognition, have been tossed about. Lately, an entire new generation of converters based on phase locked loop technology has arisen. Still, the vast majority of hams active on RTTY got their start on circuits such as covered this month. Only after one understands the fundamentals can one branch out into new areas. We'll explore some of *those* branches *another* time.

A card from Don Griffith WBØNOU was received, asking for a more detailed explanation of "space." Let's see what I can do.

Consider a wire with a voltage on it. This voltage can be either on or off. We will call the "on" state "1" and the "off" state "0". Now, if we start to turn the voltage on and off in a coded sequence, such as the Baudot teletype code, the line will demonstrate a pattern of rapidly changing 1s and 0s. *By convention*, it has become customary to call the "1" "mark" and the "0" "space." Although I used ON-OFF voltages in this example, it could have been OFF-ON keying, positive and negative, high and low, or changes in ac or rf frequency. The words "mark" and "space" denote a logic state difference, just as do "1" and "0". "Space" has *nothing* to do with the "space" character on a teletype. Any system in which a signal is coded as two states could have a "mark" and "space," even Morse code!

An overview of transmitting circuits is up for next time. Meanwhile, if anyone has specific points or questions for future columns, please send them to me at the above address, or in care of *73*.

CONTESTS

ARRL 160 METER CONTEST

Starts: 2200 GMT Friday,
December 2
Ends: 1600 GMT Sunday,
December 4

The 7th annual ARRL 160 Meter Contest is open to all amateurs on CW only. Multi-operator work is permitted and scores will be listed separately in the results, but they will not be eligible for certificates.

EXCHANGE:

RST and ARRL section or country.

SCORING:

QSOs with amateurs in an ARRL section count 2 points; QSOs with amateurs not in an ARRL section are worth 5 points. DX to DX QSOs do not count. Multiplier is the total number of ARRL sections (74), VE8, and foreign countries worked.

AWARDS:

Certificates will be awarded for section and non-W/VE country high scores. Division high scores will have their section award endorsed with an appropriate seal.

FORMS:

It is suggested that contest forms be obtained from the ARRL, 225 Main St., Newington CT 06111. Check sheets are not required, but a penalty of 3 additional contacts will be made for each duplicate contact.

These rules were taken from last year's contest. For complete rules, see the November issue of QST.

CONNECTICUT QSO PARTY

Starts: 2000 GMT Saturday,
December 3
Ends: 0200 GMT Monday,
December 5
Rest Period: 0500 to 1200 GMT
December 4

The Candlewood ARA has moved its 15th CT QSO party from the traditional first of May to the first weekend of December in an effort to find a time when band conditions are favorable and when other events are minimal. Phone and CW are considered to be the same contest. Stations may be worked once on each band and mode. Out-of-state portables and mobiles operating in CT are requested to identify themselves as such. Counties certificates will be awarded to each station working all 8 CT counties.

EXCHANGE:

QSO number, RS(T), and ARRL section or CT county.

FREQUENCIES:

SSB – 3925, 7250, 14300, 21375, 28540.

CW – 40 kHz up from bottom of each band.

SCORING:

Non-CT stations multiply total number of CT QSOs by number of CT counties worked (8 max.). CT stations multiply total number of QSOs by number of ARRL sections and provinces. Additional DX contacts count for QSO points, but only one DX multiplier is allowed overall. Q1QI, the club station, will be operating CW on odd hours, and SSB on even hours, and counts as 5 QSOs on each band and mode.

ENTRIES:

Logs must show category, date, time (GMT), calls, numbers, bands, QSO points, and claimed scores. Enclose a large SASE for results. Send logs, postmarked by Jan. 15, to CARA, c/o Fred Porter W1VH, 169 Carmen Hill Rd. Nr. 2, New Milford CT 06776.

TOPS CW CONTEST

Starts: 1800 GMT
Saturday, December 3
Ends: 1800 GMT
Sunday, December 4

General call is "CQ QMF." Entry classes for single/multi-operator. Use 3.5 to 3.6 MHz band only; use low end of band for DX-CW only!

EXCHANGE:

RST and serial number from 001.

SCORING:

Contacts with own country = 1 point; each call area in W/K, VE/VO, VK, and UA count as separate countries. Contacts with stations in same continent count 2 points, other continents = 5 points. Contacts with HQ station GW8WJ or GW6AQ count 25 points. Total score is total number of QSO points times number of prefixes worked (as per WPX award rules).

ENTRIES:

Send logs to Peter Lumb G3IRM, 14 Linton Gardens, Bury Saint Edmunds, Suffolk IP33 2DZ, United Kingdom.

How about some US participation this year? There wasn't a single entry from North America last year!

ALEXANDER VOLTA RTTY DX CONTEST

Starts: 1200 GMT Saturday,
December 3
Ends: 1200 GMT Sunday,
December 4

Two-way RTTY contacts between stations of the same country are not valid. All 2-way RTTY contacts with stations in one's own zone will count 2 points; those outside one's own zone count for points in accordance with the exchange points table. All 2-way RTTY contacts made on 7 MHz are worth double; those on 3.5 or 28 MHz are worth triple points. Stations may only be worked once per band. A multiplier of one is given for each country contacted on each band. Total score is total exchange points times the total number of multipliers times the total the total number of QSOs. Italian bonus points are added last – 1000 points for each I/IS/IT contact on all bands. Note: Each US, Canadian, and Australian District will be considered a separate country! Exchange consists of message number, RST, and zone. Use one log per band. Log forms, score sheets and exchange points table are available for IRCs. Logs must be received before Jan. 20, 1978, to qualify (advisable to use air mail). Send logs and score sheets to: A. V. RTTY DX Contest Committee, SSB & RTTY Club, PO Box 144, 22100 Como, Italy.

This contest is open to SWL RTTYers as well, and the same rules apply as used for transmitting stations; a separate results table will be made for these entries. Contest awards include callbooks, plaques, books, etc. In addition, points and positions achieved in this contest will be valid for inclusion in the "World RTTY Championship" for 1977.

Club station I2LLO will transmit a special message for 10 minutes at 2350 GMT Saturday, December 3, on 21.100 MHz at 300 Watts 170 Hz FSK, 45 baud. A special prize will be forwarded each amateur submitting a copy of the message transmitted.

ARRL 10 METER CONTEST

Starts: 1200 GMT Saturday,
December 10
Ends: 2359 GMT Sunday,
December 11

The contest is open to all amateurs worldwide. All QSOs must take place on 10 meters, and OSCAR QSOs are valid. Each station can be worked on phone-to-phone and CW-to-CW, and anyone can work anyone. All CW contacts must be made between 28.0 and 28.5 MHz, unless working through OSCAR. When operating on 10 meters, please avoid the OSCAR downlink frequencies.

CLASSES:

Entries will be classified as either single- or multiple-operator stations. Multiple-transmitter stations are not allowed.

EXCHANGE:

All W/VE stations will send RS(T) and state or province. Others will send RS(T) and consecutive serial number starting with 001. Stations that are not land-based will send RS(T) and ITU Region (1, 2 or 3). The District of Columbia is counted as part of Maryland.

SCORING:

Each completed QSO counts 2 points, or 4 points if with a W or K Novice. The multiplier is the sum of the total number of states, Canadian call areas (max. 9), ARRL countries (not US or Canada), and ITU regions from non-land-based stations. Final score is the sum of the QSO points times the total multiplier.

AWARDS:

A certificate will be awarded to the highest scoring single-operator station in each section, Canadian call area, and foreign country. Region awards for non-land-based stations, and awards for multi-operator and Novice stations will be issued if warranted.

FORMS:

It is suggested that contest forms be obtained before the contest from the ARRL, 225 Main St., Newington CT 06111; include an SASE. Check sheets are not required, but a penalty of 3 additional contacts will be made for each duplicate contact.

These rules were taken from last year's contest. For complete rules, see the November issue of QST.

HUNGARIAN DX CONTEST

Starts: 1600 GMT Saturday,
December 10
Ends: 1600 GMT Sunday,
December 11
(Unofficial)

The contest is sponsored by the Hungarian Radioamateur Society and is open to any licensed radio amateur. All amateur bands from 80 to 10 meters may be used on CW only. General call is "TEST HA," while Hungarians will give "TEST WW." Entries may be in any of the following classes: single op, single band; single op, multi-band; or multi-op, multi-band.

CALENDAR

Dec 3-4	**ARRL 160 Meter Contest**
	TOPS CW Contest
	Alexander Volta RTTY Contest
	EA Phone Contest
Dec 3-5	**Connecticut QSO Party**
Dec 10-11	**ARRL 10 Meter Contest**
	EA CW Contest
	HA DX Contest
Dec 17-18	**SOWP CW Christmas party**
Dec 31	**Straight Key Night**
. . . 1978 . . .	
Jan 14	**Hunting Lions in the Air Contest**
Feb 11-12	**Ten-Ten International Net Winter QSO Party**
Aug 19-20	**NJ QSO Party**

EXCHANGE:

RST and continuous serial number from 001. After their signal report, Hungarian stations will give a two-letter code for their location (county) as follows: BA, BP, BE, BN, BO, CS, FE, GY, HA, HE, KO, NO, PE, SA, SO, SZ, TO, VA, VE, ZA.

SCORING:

Each HA QSO counts 1 point. The same station may be worked only once per band. Each different HA county worked counts 1 multiplier point per band. Final score is total QSO points times sum of multiplier points from each band.

ENTRIES:

Logs must be made in usual form with summary sheet and signed declaration. They should be mailed within 6 weeks after the contest to: Radio Amateur League of Budapest, H-1553 Budapest, P.O. Box 2, Hungary.

AWARDS:

Certificates to first place station from each country in each class or section. Additional places if warranted.

1977 CW CHRISTMAS PARTY

The Society of Wireless Pioneers (SOWP) is planning a membership Christmas on-the-air CW QSO Party for the weekend of December 17 and 18, 1977. The party will cover the full GMT period to allow members around the world to participate. This will be the second Christmas on-the-air party held by the Society.

The purpose of the affair will be to give members an opportunity to meet on the air and to exchange Season's Greetings. There will be no formal exchange requirements and no need for members to submit logs, etc.

All members with amateur licenses are being encouraged to take part. The call will be CQ SOWP. While there will be no certificates or other awards given, everyone who takes part will be a winner by having an opportunity to renew old friendships, establish new ones, and continue a camaraderie developed over the years.

Suggested frequencies for the party are 55 kHz up from the low end of each amateur band. Additional information about this party and the Society can be obtained from the Party Coordinator, Bill Willmot K4TF, 1630 Venus Street, Merritt Island, Florida 32952.

ARRL STRAIGHT KEY NIGHT
0100-0700 GMT Sunday, January 1

Check *QST* for any changes in the rules!

Basically, rules require the use of a straight key only. Send "SKN" instead of "RST" during QSOs, to help identify contest stations. On 80-40-20 meters, try 060 to 080 kHz up from the bottom edge of the band. On Novice bands, try 10 kHz up from the bottom of the Novice band. After the contest period, send a list of calls of the stations contacted during the contest period, plus your vote for the best fist heard. Please mail entries as soon as possible to the ARRL, 225 Main Street, Newington CT 06111.

WORKED ALL NEW ENGLAND AWARD

For working stations in each of the 6 New England states on 50 MHz band or higher. Endorsements on request for all ATV, SSB, CW, OSCAR, etc. All contacts must be on or after Jan. 1, 1976. W/K1 stations work two stations from each state, other work only one station in each state. Send log consisting of date, time, call, name, and state, along with check or money order for $1.50 (DX send 2 IRCs) to: Worked All New England Award, Ronald Pariseau, Chairman, R1 Box 213A, Thompson CT 06277. Make checks payable to Ron Pariseau, Chairman.

TRI-STATE CERTIFICATE

Award is for working stations in the Tri-States of Connecticut, Massachusetts, and Rhode Island. Contacts must be made on or after Jan. 1, 1977. W/K1 stations must work three stations from each state; other call areas and DX stations work one station from each state. QSLs must be in your possession, but need not be sent with application. Cards may, however, be requested later. Log will consist of date, time, call, name, state. The award is open to all amateurs on all bands; hand-written endorsements are available on request. Send logs and $2.00 check or money order to: Tri-State Amateur Radio Club, Award Committee, Box 213A R1, Thompson CT 06277.

New Products

SINGLE CMOS CHIP MAKES INEXPENSIVE 3-3/4 DIGIT PANEL METER

A new addition to the National Semiconductor data conversion line is the "ADD3701," a single CMOS integrated circuit which requires only a display, an external voltage reference, and a digit driver to form a complete 3-3/4 digit DVM (digital voltmeter) that reads up to 3.999 units.

Manufactured using standard CMOS technology, the ADD3701 is an extended-range version of National's "ADD3501" 3½ digit DVM introduced earlier this year, with readings up to 1.999. The additional range of the new DVM chip expands the applications of the device into areas where a reading of 1.999 isn't high enough, such as weight measurement on bathroom scales and measurement of degrees of rotation or temperature.

The ADD3701 utilizes a single five-volt supply to drive a multiplexed seven-segment output directly, and features differential input protection to 200 volts. Overrange condition is displayed by "+OFL" or "-OFL" indication, depending upon whether the input voltage is positive or negative.

The 3701 also features auto-polarity and an on-chip clock that eliminates the need for an external signal timing circuit. This internal oscillator can be set by an external RC network, or the oscillator can be driven from an external frequency source.

When using the external RC network, a square wave output is available. It is important to note that great care has been taken to synchronize digit miltiplexing with the A/D conversion timing, to eliminate noise from power supply transients.

A pulse modulation analog-to-digital conversion method is used, requiring no external precision components. The seven-segment outputs are capable of delivering up to 40 milliamps per segment, making the ADD3701 ideally suited to drive 0.5-inch and 0.7-inch common cathode LED displays. The price of the model "ADD3701CCN" is S11.95 when purchased in lots of 100. Delivery is from stock. *National Semiconductor, 2900 Semiconductor Drive, Santa Clara CA 95051.*

THIRD HAND

That's what you need when you are working on PC boards — they just won't hold still. One of our readers out in Hawaii came up with a little clamp arrangement (which is being marketed by a firm in California) called the 3rd Hand. You clamp one part of it to your table, anything from 3/4" to 1½" thick, and then clamp the other part of the gadget to the PC board. There is a piano hinge between the two parts so you can flip the PC board over and work on both sides.

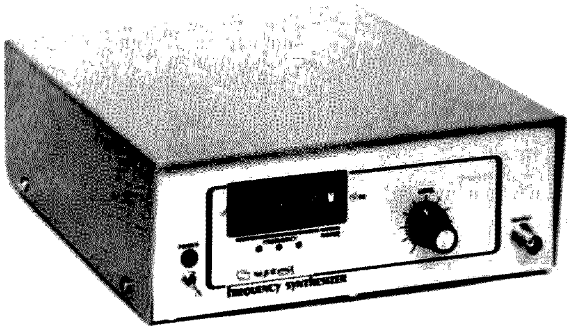
It sells for S6.95 plus postage, tax, etc. *3rd Hand, Box 60579, Sacramento CA 95860.*

TERMINAL STRIPS FOR PC BOARDS

The TS series of terminal strips provides solderless termination of wire leads via positive screw-activated clamping action. Strips are available with 4, 8, or 12 positions, and accommodate wire sizes 14-30 AWG (1, 8-0, 25mm). Pins are silver-plated brass, .040 inch (1mm) diameter, on .200 inch (5mm) centers. Features include unbreakable polyamid bodies and consecutively numbered terminals. Rated 10 Amps at 300 V. In stock for immediate delivery from *O.K. Machine and Tool Corporation, 3455 Conner Street, Bronx, New York 10475.*

SYNTEST SI-101 FREQUENCY SYNTHESIZER

The Syntest Corporation Model SI-101 frequency synthesizer provides excellent general purpose performance at low cost. Typical applications for the Syntest SI-101 instrument include use as a calibration standard for test instrumentation, as a precision programmable clock for systems use, and for the alignment of active filters.



Syntest's Model SI-101 frequency synthesizer.

The Model SI-101 features 4½ digits of resolution from 0.1 Hz to 16 MHz. A high stability internal reference oscillator, ±10 PPM over the temperature range 0-50° C, and fast programming highlight this versatile instrument. The synthesizer provides a continuously adjustable 50 Ohm TTL output. The unit is completely solid state and incorporates a rugged power supply for high reliability.

Power requirements are 115 or 230 V ac, rear panel switch selectable, at 5 W maximum consumption. The SI-101 is housed in an attractive 8.50" W x 3.20" H x 9.00" D enclosure.

An industry standard RETMA rack mount adaptor, as well as a ±1 PPM reference oscillator, are offered as options. Custom configurations are available from the factory.

Price of the Syntest SI-101 frequency synthesizer is $459.00 in unit quantities and availability is stock to 30 days. *Syntest, 169 Millham Street, Marlboro MA 01752.*

NEW 1978 RADIO SHACK CATALOG #289 ISSUED

The new 1978 Radio Shack Catalog, the company's 30th consecutive issue, is now available from Radio Shack stores and dealers, nationwide.

The 164-page catalog includes 100 full-color pages describing the company's exclusive line of products for home entertainment, hobbyists, CBers, and experimenters.

An insert card in the catalog introduces Radio Shack's new TRS-80 Microcomputer System, which, according to Radio Shack president Lewis Kornfeld, is "the most important product ever offered by Radio Shack."

"The TRS-80's importance," Kornfeld stated, "goes far beyond the mere design, construction, and sale of the fine piece of electronic merchandise. Primarily, it signifies the dawn of the microcomputer age in respect to availability and affordability to ordinary people, schools, and businesses every-

National Semiconductor's ADD3701 single CMOS chip.

where, even for personal use and entertainment.

"Secondarily, the TRS-80 should convince millions of folks that Radio Shack is a technological company as well as a marketing company."

The new catalog also includes coupons offering two Supertapes, either reel-to-reel, 8-track cartridge, or cassette, for the price of one, two P-Box kits for the price of one, and any of the company's project boards for half price.

Among the new items introduced in the catalog are 40-channel Realistic CB two-way radios and a selection of electronic calculators ranging in price from $8.88 to $109.95 for a rechargeable printing calculator with full memory.

The new catalog also lists hundreds of specialized electronics items, parts and accessories, tools, tubes, semiconductors, wire and cable, intercoms, microphones, timers, batteries, and a complete library of Radio Shack's own books on electronics and related subjects.

Radio Shack's 1978 Catalog #289 is available free on request from Radio Shack stores and dealers, nationwide.

Radio Shack, a division of Tandy Corporation (NYSE), has more than 6,000 stores and dealers in all 50 states and Canada, and nearly 500 stores overseas operating under the name Tandy International Electronics. *Tandy Corporation, 2617 West Seventh Street, Fort Worth TX 76107.*

CLEGG COMMUNICATIONS PROFILE

It was a nice day in early May, a nice day to take a ride from Valley Stream, New York, where I was staying, to a more pleasant place. Early in the morning, I drove into Brooklyn to pick up Larry, who had agreed to leave his homemade computer for the day and act as my photographer on this assignment. Our destination some 90 miles away – Lancaster, Pennsylvania, the home of Clegg Communications and the man behind the name, Mr. Edward T. Clegg W3LOY.

The three-hour ride from Brooklyn gave us a chance to reminisce about the old days, the time when VHF meant six meter AM, a time when Clegg reigned supreme. I can remember it as if it were yesterday, though it's now over 16 years ago. I remember my very first transceiver – a rather pretty gray and white box that ran 7 Watts at 100% modulation and featured a super sensitive state-of-the-art (of that day) receiver that gave the popular receiver/converter combinations a good run for the money. I remember placing this little box atop Larry's SX-28 and Techcraft converter to make a comparison. I can even picture the expressions on our faces when we found that the transceiver could hear as well as the Techcraft SX-28 combo. Not a very scientific test, I will admit, but for a pair of teenagers, it was all we needed to be convinced. The radio we literally fell in love with was known as the 99er, and it came from the man we would soon see. The Clegg 99er – a radio that set the industry and six meters both on their proverbial ears, especially when it came on the market at a price that was half of anything comparable.

The 99er was not the first radio from Clegg, nor was it to be the last. Fact is, Ed Clegg was designing and marketing VHF communication equipment for amateur use well before most of the competition considered it fashionable. The 99er was my first personal exposure to the famous "Clegg line," a line of amateur VHF equipment that down through the years has always managed to stay a jump or two ahead of competitors. There was the Thor VI – 60 Watts AM with a VFO that automatically tracked the transmitter to the receiver (commonplace today in HF and VHF SSB, but this was the early sixties and six AM). SSB came to six in the mid-sixties, and one of the first entries was the Venus and its matching Apollo linear amplifier. And who can ever forget the Cadillac of VHF – the radio twins that meant you were on the top – the Clegg Zeus transmitter and matching Interceptor receiver.

When we found FM and two meters, Clegg had already discovered it. The AM 22er gave way quickly to the 22er FM, which eventually itself gave way to the first fully synthesized radio to hit the US marketplace – the famous FM-27, 27A, and 27B. These radios, five to seven years old, still bring a pretty penny at resale time. The FM-27 series of radios was designed to last as long as two meters lasts, regardless of what band plan or split may be in use. It would work anywhere, and that sold it. Soon though, in many cities, two meters was bulging at the seams with activity. What to do? Move up, up to 220 MHz. Again, Clegg was first with his FM-21, a radio that used but one crystal to get both the transmit and receive channels. The FM-21 that . . . we're here . . . the time has flown.

Not one to tarry, Larry set to work photographing everyone and everything in sight while I sat down to eyeball with Ed. We spoke of many things – pending rulemaking, the ARMA organization that Ed is a member of, and finally, the current line of equipment. No matter how much or how little you have to spend, there is a radio in the Clegg line to fill your need. AM has given way to FM, and the entire line shows this. Two meters? We start with the MK-3 – fifteen Watts and twelve channels in a neat little box that comes complete with mic, mic hanger, and mounting bracket. The receiver is double conversion and the price is well under the $200 mark.

Want to be able to work any channel you desire and never have to purchase a crystal? Clegg has two radios that will meet your criteria. At around the $350 mark, there is the FM-28. For your money, you get full 144 to 148 MHz coverage, LED readout, 600 kHz up/down for repeater use, option of other offsets, 5 kHz split ability for repeaters on tertiary channels, and one of the best sounding transmitters found on the air these days.

Top of the Clegg 2 meter line is the FM-DX, a radio that has become a legend in its own time. Fully digitally synthesized with 40 Watts out and coverage from 143.5 to 148.5 MHz, letting the owner work MARS services if he is so associated, along with every other feature that the avid two meter FM enthusiast might want (except a built-in tone pad), the FM-DX is a radio appreciated by many discriminating amateurs. It's not inexpensive, but even at its approximate $600 price, it's well worth the money. Those amateurs who own the FM-DX will settle for nothing else. That says a lot in itself.

Not that two meters is the only interest of Ed Clegg and his company. Two meters in many places is getting really crowded. With an eye to the future, about five years ago Clegg was the first on the market with a 220 MHz radio designed and priced for the

Looking West

Bill Pasternak WA6ITF
24854-C Newhall Ave.
Newhall CA 91321

The news about 21033 first reached this area at about 7:30 pm on the evening of September 23, in the form of a telephone call from Jay O'Brien W6GO to Jim Hendershot WA6VQP, current SCRA chairman. It took everyone quite by surprise.

THE BIG CHANGE IS ON TWO

Probably of most significance to the average ham is the deregulation of a second subband on two meters for relay communication. This does not mean that repeaters *must* be placed in the segment from 144.5 to 145.5 MHz. Rather, it gives us the *option* to do so if we wish. In deregulating this new subband, the FCC has alarmed many of the amateurs who specialize in other aspects of VHF, such as SSB, EME experimentation, and local AM rag chewing. Needless to say, these people have been less than enthusiastic about this change, and in some areas organized non-FM groups have already declared "war" on any attempt to channelize this portion of two meters and assign repeaters to it. While no FM group wants such a confrontation to develop, it is likely to happen in some places.

Coordinators probably face their biggest challenge yet. Not only must they deal with the needs of those amateurs involved in relay communication, but they also will have to come to terms with non-relay-oriented groups. Remember, during the early days of coordination, councils were dealing for the most part with spectrum that was usually vacant and unused.

Groups of amateurs involved in non-relay communication have banded together over recent years in an effort to preserve their special interests and help foster the growth of such interests. A well-known and successful Texas organization of this kind is Sidewinders-On-Two. Here in Southern California, we now have a local chapter of SWOT, and this organization has been growing. To do well, the coordinator of today must deal with the needs of the non-relay-oriented amateurs on a basis equal to that of those involved in FM relay communication.

TWO METER BAND PLANS

In the five days since the deregulation, several potential band plans have been proposed. There is the right-side-up 20 kHz plan with built-in protection for non-FM interests, already adopted by the Northern Amateur Relay Council at a meeting on 9/25/77, at least two 30 kHz plans following the system used between 146 to 148 MHz (with the only difference between the two being which way the 15 kHz splits will go), and, finally, the proposal that 100 kHz translators, rather than repeaters, should be coordinated within that spectrum so as to be compatible with existing and future activity. Only the NARC 20 kHz plan and the translator idea take any great pains to protect the interest of already existing activity. The other plans seem to look out mainly for the welfare of those involved in repeaters.

As outlined by Jay O'Brien W6GO, here is the NARC plan, along with their reasons for adopting it: There would be twenty repeater channels with 600 kHz input-output spacing. 144.9 through 145.1 MHz would be left open for direct (simplex) communication of any kind. Repeater inputs would be 144.51 through 144.89 MHz. Repeater outputs would be 145.11 through 145.49 MHz. Channel spacing would be 20 kHz.

Rationale: 1) since the FCC did not allow the Technician SSB activity to relocate to 144.0 MHz, the present activity at 145.0 MHz is respected by the provision of the 200 kHz non-FM band; 2) channel spacing was selected to provide 20 completely usable channels spaced 20 kHz, instead of 26 unsatisfactory channels spaced 15 kHz – they were persuaded not to repeat the 15 kHz spacing error made in the 146 to 148 MHz band; 3) input low was chosen to place possible intermodulation products in the repeater band rather than in the 144.0 to 144.5 or 145.5 to 146 MHz segments.

As far as "band plans" go, this is the first to be adopted by any coordination group. It's a good one technologically-speaking, and tries to serve the needs of the non-FMer. To date, it's the only one that has met with any degree of acceptance from the non-FM amateur community.

While NARC went out of its way to give protection to non-FM interests, not everyone has. For instance, a plan similar to the NARC plan calls for the same 20 repeaters, the same 200 kHz in/out separation, and the same 20 kHz spacing between systems – but it also specifically channelizes 144.9 to 145.1 again on a 20-kHz-between-channels basis for FM point-to-point communication *only*. This is a selfish attitude, and one that any sane coordinator must avoid like the plague. Adoption of channelized FM operation in the 144.9 to 145.1 spectrum would lead to wars.

There has been but one good 30 kHz plan to date. It calls for 30 kHz between systems, 600 kHz between input and output, inverted 15 kHz channels for additional repeaters, and a non-FM simplex band between inputs and outputs. The major problem with this is twofold. First, while yielding a total of 26 possible additional repeater pairs, past experience has proven that 15 kHz splits, even when inverted, are marginal at best. The 15 kHz split was born out of necessity in the 146 to 148 MHz spectrum, when we ran out of 30 kHz pairs. The east coast went right-side-up, placing the selectivity burden on the user's receiver, while out west we went inverted, feeling that it was easier for repeaters to solve these problems than for thousands of users. Time has proven us right, and even the ARRL now endorses the inverted plan. However, since we have a chance to do it right this time, why not do it right? 30 kHz with 15 kHz splits gives quantity, but wouldn't we do better with 20 quality systems?

THE LINEAR TRANSLATOR ISSUE

Do we really need more 2m FM repeaters? Here in Southern California, and in some Texas circles as well, consideration is being given to the implementation of coordinated 100 kHz linear translators compatible with any and all modes of operation that any amateur might want to use. Unlike with channelized repeater operation, translators permit an amateur to "roam free," VFO-controlled, to locate the person or persons he may choose to QSO with.

In essence, a translator is a wide band repeater that has the ability to "repeat" individual signals it hears in one given segment of spectrum, on an individual basis, to a specific point within another given segment of spectrum. A good example of this is the OSCAR satellites. These spacecraft contain translators which listen on 430 MHz or two meters and "repeat" *individual signals* heard back to Earth on either two meters or 10 meters, depending upon the mode in which the OSCAR is functioned.

Translators in the amateur service have previously been crossband, like OSCAR. Are in-band translators possible for a 600 kHz separation between input and output? Experts disagree. It would be a challenge worthy of amateur radio pioneers.

220: TWO METERS, YOU'RE NOT ALONE!

While this deregulation will not affect 220 in many places for a while, here in Southern California we are already into multiple coordinations in that band. For some time, the SCRA has been under pressure to start the coordination of repeaters below 222.30 MHz. There has also been an opposing pressure from non-repeater groups such as the Los Angeles 220 Association. So where do we put all the link and control channels wanted on 220? There is no room on 450 for them, and there is already a lot of money tied up in equipment. Southern California already has over 300 repeaters operational on 146 and 220. Just how many more systems are needed, anyhow? Every week, the SCRA gets at least a half dozen requests for repeater frequencies on 146 or 220. Most of these requests are for wide coverage systems rather than the local type (which are really what are needed). Where do you put them? What do you say to them? When will it end?

On 220, simplex is alive and well in the form of the 220 Rag and Tech Net. These chaps are determined to perpetrate the current SCRA band plan. They make no bones about it; they will not accept further relay operations, other than remote base stations which are compatible with simplex. At present, they are about equal in number to the repeater enthusiasts, and just as technologically competent. The SCRA and 220 simplexers have been getting along well with each other so far. This may be an area in which the translator concept might work. This problem is already in the hands of Tom Rutherford's SCRA 220 Technical Committee and the delegates of the 220 simplex group.

WHERE'S 450 IN ALL THIS?

With the emphasis on two meters and 220, the simultaneous deregulation of 420 to 450 MHz has been lost in all this. What about 450? What will happen there? The Southern California Repeater and Remote Base Association, which coordinates the 420 to 450 MHz spectrum, has issued no comment to date. The unofficial input indicates that little will change. UHF relay enthusiasts seem quite elated at the deregulation aspects of portable and mobile operation of auxiliary link stations, as this is important to successful remote base system operation. Otherwise, local UHF people involved in relay communication have been very silent on the entire issue.

GOODBYE WR

I can still remember the verbal abuse aimed at the FCC in the early '70s when we found out that we had to get a special WR call for our repeaters. We hated them at first . . . but . . . lo and behold . . . now that the time has come to place them to rest . . . what's this? . . . abuse again!

THE FINAL WRAPUP

Obviously, this has been written in great haste. It's been based upon personal contacts with amateurs around the nation as well as here in California. If it seems to dwell on what California faces and how it's meeting the new challenge that is inherent to this deregulation, it's only because California really typifies what is probably happening nationwide. Since I am part of it, it is easier to be accurate in writing about it. I am sure that in these pages, now and in coming months, you will be reading much about the feelings of others on all that has transpired.

If I seem down on repeater expansion, it's only because I really wonder just how many repeaters any one area needs to serve its amateur population.

Perhaps it's time that we amateurs take another step forward and do something truly constructive, something that amateurs generations from now will look back upon with pride. Whether it be translators or some other exotic device not dreamed of yet, the FCC has given the amateur of 1977 a chance to be again looked upon as the technological communication leader. It's in our hands.

FCC

DOCKET 21033

1. Repeater, auxiliary link and control stations eliminated.
   - Immediate freeze on filing repeater, auxiliary link and control station license applications.
   - Applications for new repeaters on file dismissed.
2. Portable and mobile operation of auxiliary links approved.
3. No more "WR" callsigns for stations in repeater operation.
4. Stations operating as repeaters have to identify with the word "repeater" on phone or the letters "RPT" on CW, in addition to the station callsign.
5. Stations operating as auxiliary links have to identify with the word "auxiliary" on phone or the letters "AUX" on CW, in addition to the station callsign.
6. ID interval increased from 5 to 10 minutes.
7. Transmissions from open-access automatically-controlled repeaters need no longer be monitored or recorded.
8. 144.5-145.5 MHz and all frequencies above 220 MHz made available for repeaters (except 435-438 MHz).
9. Technicians given privileges on 144.5-145.0 MHz.
10. No action on priority in frequency use, erp.

PART 97—AMATEUR RADIO SERVICE

Simplifying the Licensing and Operation of Complex Systems of Stations and Modifying Repeater Subbands in the Amateur Radio Service

AGENCY: Federal Communications Commission.

ACTION: Final rules.

SUMMARY: The FCC is revising its amateur radio rules to eliminate separate licenses for repeater, auxiliary link, and control stations. We are also allocating additional frequencies for amateur repeater operation, and we are making minor revisions of the rules concerning logging and identification for stations in repeater operation and remotely controlled stations. Adoption of these rules will afford amateur licensees greater flexibility in their operations.

SUPPLEMENTARY INFORMATION: In the matter of Deregulation of Part 97 of the Commission's Rules to simplify the licensing and operation of complex systems and stations and modify repeater subbands in the Amateur Radio Service (Docket 21033, RM-2664, RM-2780). Report and Order (Proceeding Terminated).

Adopted: September 21, 1977.

Released: September 27, 1977.

WHAT IS THE BACKGROUND OF THIS PROCEEDING?

1. In a Notice of Inquiry and Notice of Proposed Rule Making in Docket 21033 released January 6, 1977, 42 FR 2089 (1977), the Commission acted partially in response to rule making petitions RM-2664 and RM-2780, submitted by Messrs. Gordon Schlesinger and William F. Kelsey and The Middle Atlantic FM and Repeater Council (T-MARC), respectively, and partially on its own motion. The Commission proposed substantial revisions to Part 97 of its Rules, 47 CFR 97.1, et. seq., concerning the licensing and operation of repeater, auxiliary link, and control stations in the Amateur Radio Service. Other proposals concerned the licensing and operation of remotely controlled stations in the Amateur Service. Comments on our proposals were due no later than April 1, 1977. Reply comments were due no later than April 15, 1977. The deadline for the submission of reply comments was subsequently extended by the Chief of the Commission's Safety and Special Radio Services Bureau to April 29, 1977. We are now prepared to take action on our proposals in this proceeding.

WHAT WERE THE COMMISSION'S SPECIFIC PROPOSALS?

2. In our Notice of Inquiry and Notice of Proposed Rule Making in this proceeding, we made a number of proposals concerning the licensing and operation of complex systems of stations in the Amateur Service, which, if adopted in their entirety, would have had a significant impact on amateur licensing. Briefly summarized, our proposals in Docket 21033 were as follows:

a. We proposed to eliminate separate licenses for repeater, auxiliary link, and control stations. Operations now conducted by such stations would be permitted all remaining amateur stations without prior Commission approval under new forms of station operation to be known as "repeater operation" and "auxiliary operation".

b. We proposed no longer to require that an applicant wishing to operate a radio remotely controlled station obtain prior Commission authorization.

c. We proposed to permit portable and mobile operation by stations in auxiliary operation. (Auxiliary link stations are presently restricted to operation from a fixed location.)

d. We proposed to discontinue the issuance, in most instances, of call signs with "WR" prefixes to stations in repeater operation.

e. We proposed to require that stations in repeater and auxiliary operation transmit distinctive station identifications.

f. We proposed to increase the minimum interval at which stations in repeater operation must identify from five to ten minutes.

g. We proposed to delete the current requirement that transmissions from stations in repeater operation under automatic control either be recorded or monitored in real time by a duty control operator.

h. We proposed to require that the logs of all remotely controlled stations contain a list of all authorized control operators.

i. We proposed to require that a photocopy of the remotely controlled station license and a list of authorized control operators be posted conspicuously at the remotely controlled transmitter site and the station location of each control operator and be carried by each control operator operating a remotely controlled station from a portable or mobile control point.

j. We proposed to require that the antenna or mast associated with a remotely controlled transmitter bear a durable tag, marked with the remotely controlled station call sign, and the name of the station licensee and all authorized control operators.

k. We proposed to make all authorized amateur frequencies, except 435 to 438 MHz, available for repeater and auxiliary operation.

l. We proposed a new rule stating that a station occupying a frequency has priority in its use over other stations, and that all frequencies in the Amateur Service must be shared.

m. Finally, we requested comments concerning present and future anticipated interference patterns, the adequacy of current techniques for keeping interference to a minimum, and the adequacy of present voluntary spectrum management systems. We also asked for comments concerning the utility of the limitations on the effective radiated power (ERP) of stations in repeater operation contained in Section 97.67 of the Rules.

WHY DID WE MAKE THESE PROPOSALS?

3. Our purpose in issuing the Notice of Proposed Rule Making in this proceeding was to continue the relaxation of amateur regulations governing the licensing and operation of complex systems of stations. We stated in our Notice that since adoption in 1972 of regulations governing the licensing and operation of repeater and associated stations, (Report and Order, Docket 18803, 37 FCC 2d 225 (1972)), we have become increasingly convinced that amateur licensees could develop and operate complex systems of stations with a minimum of Commission regulation. Accordingly, in 1974 we began reducing the unnecessary burdens imposed on licensees of repeater and associated stations. In a series of rulemaking proceedings, we deleted the requirements that certain technical data be submitted with applications for repeater and remotely controlled stations and relaxed the rules to permit the linking, automatic control, and crossband operation of repeater stations. This proceeding is, in part, an attempt to provide amateur operators even greater flexibility in their operations and to create a more favorable regulatory atmosphere for the Amateur Radio Service.

WHO COMMENTED ON OUR PROPOSALS?

4. We received 86 timely comments in response to our Notice of Proposed Rule Making. Of these, 24 were submitted by clubs or other organizations. We received two timely reply comments. Twenty-four comments and one reply comment were received too late to be considered in this proceeding.[1] A list of those submitting timely comments in response to our Notice is contained in Appendix I.

WHAT DID THOSE COMMENTING ON OUR PROPOSALS SAY?

5. The number of comments we received makes it impossible to discuss each comment individually. Each comment has been read and carefully evaluated by the Commission's staff, however. Most of the comments received supported some aspects of our proposals but opposed others. In general, opposition was greatest to the major proposals. The less significant proposals were generally favored. In capsule form, the comments on our proposals were along these lines—

a. Most respondents argued that separate licenses for repeater stations should be retained. To eliminate separate repeater station licenses would, it was alleged, encourage "pirate" or "fly-by-night" repeater stations, and, in the words of T-MARC, permit "any amateur to, on a moment's notice, decide [sic] to operate as a repeater." Comments, The Mid-Atlantic FM and Repeater Council at 1. Others stated that operation of a repeater station is a serious and often expensive matter, and that effective spectrum management planning and coordination require that an amateur be placed on notice, by means of a separate repeater station license application, that "something more than the grant of a simple application is required." Comments, American Radio Relay League, Incorporated (ARRL) at 15.[2] On the other hand, our proposal to delete separate licenses for auxiliary link and control stations and create another form of amateur operation known as "auxiliary operation" met with general approval. Few comments specifically addressed the proposed deletion of the requirement that authorization from the Commission be obtained before remote control operation is undertaken, but of those that did, most approved.

b. Our proposal to permit auxiliary operation from control points in portable and mobile operation was nearly unanimously accepted. Operators of remotely controlled base stations were particularly enthusiastic, because adoption of this proposal would permit them to operate their remotely controlled stations from portable and mobile locations, a practice not currently allowed.

c. Most of our respondents wished to retain distinctive call signs for stations in repeater operation and requested that the practice of issuing call signs prefixed by the letters "WR" to such stations be continued, whether or not such stations are actually licensed as repeater stations. The ARRL, among others, argued that a distinctive call sign for a station in repeater operation is necessary to let those monitoring know a station in repeater operation is on the frequency. Because most comments favored distinctive call signs for stations in repeater operation, they opposed any other form of special identification for stations in repeater operation, although there was some support for requiring a station in auxiliary operation to transmit a distinctive identification. Our proposal to increase from five to ten minutes the minimum interoperation to transmit a distinctive identification must identify was widely supported in the comments.

d. The vast majority of our respondents urged the Commission to adopt the proposal to delete the requirement that transmissions from open access automatically controlled stations in repeater operation either be recorded or monitored in real time. Many of the comments went further, however, and offered a suggestion outside the scope of this proceeding, namely, that stations in repeater operation be exempted from the third party traffic logging requirements of Section 97.103(b)(2) of the Rules. Not to modify third party traffic logging requirements for open access automatically controlled stations in repeater operation would, in the words of the ARRL, "render the Commission's proposed relaxation * * * a nullity in terms of practical application * * *." Reply Comments, ARRL at 6.

e. Our proposals to modify slightly the logging requirements for remotely controlled stations, to require the posting of certain information at the remotely controlled transmitter site, and to require that a durable tag bearing certain data be attached to the remotely controlled transmitter antenna were relatively uncontroversial. Opposition was expressed to the durable tag proposal, however. The Northern Amateur Relay Council (NARC) of California, for example, stated that such tags are easily stolen or lost and that a requirement of this sort would be an unfair burden on licensees operating stations at truly "remote" locations.

f. Our proposal to make all amateur frequencies available for repeater and auxiliary operation was the subject of intense criticism by nearly all respondents. Although a few groups, such as NARC, welcomed the opportunity to experiment with the possibilities such a relaxation would have offered, the vast majority of the comments opposed such a radical change. Virtually all those commenting opposed any expansion of the repeater subbands below 28 MHz. They stated that there is no demonstrated need for repeater operation in the high frequency range, and that such an expansion would create many more problems than the increased flexibility in repeater operation would justify. Similarly, the majority of those submitting comments opposed making all very high frequency (VHF) and ultra high frequency (UHF) bands available for repeater operation. Concern was especially acute over opening all frequencies in the two meter band (144-148 MHz) to repeater operation. Respondents such as the Radio Amateur Satellite Corporation (AMSAT) stated that certain amateur activity in the two meter band must be provided protection from repeater operation. This activity, which typically involves the reception of weak signals, is said to be incompatible with channelized repeater operation. Many other respondents, such as T-MARC, agreed that weak signal work must be protected but argued that there is a definite need for additional two meter frequencies for repeater operation. The ARRL said that it may well be desirable to increase the allocation for repeater operation in the amateur two meter band but urged that any such expansion be the subject of a separate rule making proceeding.

g. Our proposed new rule concerning priority in usage of a frequency was overwhelmingly opposed. Most respondents said the proposed rule was inherently (if necessarily) vague and that its adoption would create more problems than it would solve. The general belief appeared to be that existing rules and practices are working reasonably well, and that, absent a compelling indication to the contrary, the Commission should take no action in this area at the present time.

h. In response to our inquiries concerning the adequacy of the current system of voluntary spectrum management and the necessity for the limitations on the effective radiated power of stations in repeater operation contained in Section 97.67 of the Rules, we received many informative and helpful responses. These comments indicated, generally, a widespread dissatisfaction with the ERP limitations on repeater operation, as well as a belief that the Amateur Service's voluntary spectrum management system functions with considerable effectiveness in most instances.

WHAT RULES ARE WE ADOPTING AND WHY?

6. After a careful analysis of our proposals and the comments submitted in response to our proposals, we have decided that the public interest will be best served by the following action—

a. We are eliminating separate re-

[1] The Commission's practice of informally accepting comments in rule making proceedings after the comment due date was recently held to be a violation of Section 1.415 of the Rules. *Home Box Office, Inc. v. Federal Communications Commission*, —— F.2d —— (D.C. Cir. 1977).

[2] The ARRL's Comments in this proceeding were filed late but were accompanied by a Motion to Accept Late Filed Comments. We are granting the ARRL's Motion.

peater, auxiliary link, and control station licenses, as proposed. Operations now conducted by such stations will be authorized other stations without prior Commission approval under new forms of amateur operation to be known as "repeater operation" and "auxiliary operation." We believe the contention that elimination of separate repeater station licenses will encourage "fly-by-night" repeater operation is frivolous. As the Iowa Repeater Council noted in its Comments, "[r]epeaters are expensive. They take a lot of hard work * * *." Comments, Iowa Repeater Council at 6. We doubt very much whether anyone willing to expend the time and effort necessary to place a station in repeater operation will do so on the spur of the moment. We simply do not believe that the incidence of so-called "ego-trip" repeaters will be any greater under the new rules than it is presently. The assertion made by T-MARC (and others) that elimination of separate licenses for stations in repeater operation will permit a licensee to decide "on a moment's notice" to engage in repeater operation is no more tenable now than it was before the adoption of rules for repeater stations in Docket 18803 in 1972. (Moreover, as NARC observed in its comments, absence of a repeater station license does not necessarily inhibit repeater operation under the existing rules. A licensee wishing to put a repeater station in operation need only find the licensee of an existing repeater station willing to share the responsibility of repeater operation from a portable location. The first licensee then operates a portable repeater station under the authority of the existing repeater station license.)

Further, processing and issuing repeater, auxiliary link, and control station licenses is much more complex than processing and issuing simple primary station licenses. Different data bases must be maintained, and FCC staff must be detailed to perform these specific functions. In sum, although repeater stations are relatively few, in comparison with the population of the Amateur Radio Service as a whole, their impact on the processing of other amateur licenses is far out of proportion to their number. Elimination of separate repeater, auxiliary link and control stations will enable us to provide the public with better service in other, more important areas, such as the processing of Novice Class and other classes of operator license applications.

Accordingly, beginning with the effective date of this Report and Order, no more licenses for repeater, auxiliary link, or control stations will be issued. Existing repeater, auxiliary link, and control stations may continue to be operated until expiration of their station licenses. Such licenses will not be renewed. Further, in order to continue the efficient processing of other amateur radio license applications, effective with the adoption of this Report and Order by the Commission we are imposing a "freeze" on the filing of applications for new, modified or renewed repeater, auxiliary link, and control station license applications. The freeze will continue until the date the regulations adopted in the Report and Order become effective.

We find that the public interest will be best served if the applications for new repeater station licenses presently on file are dismissed, and we hereby do so. Pending applications for renewed repeater station licenses or modified repeater station licenses will be processed, however.

b. *We are authorizing auxiliary operation from control points in portable and mobile operation.* This amendment, which was unopposed by the comments, will afford operators of remotely controlled stations much greater flexibility in their operations. It will permit operators of remotely controlled stations to operate their stations as they would locally controlled stations, without many of the previous restrictions placed on them.[3]

c. *We are discontinuing our practice of issuing call signs prefixed by the letters "WR" to stations in repeater operation.* We do not believe "WR"-prefixed call signs are a necessary aspect of repeater operation in the Amateur Service, any more now than they were before the regulations adopted in Docket 18803. We are aware, however, of the desire of many of those submitting comments in this proceeding, such as the ARRL, for rules ensuring that those monitoring a frequency know there is a station in repeater operation using that frequency. For this reason, we are adopting regulations as proposed requiring distinctive identification for stations in repeater and auxiliary operation. Stations in repeater operation will be required to transmit the letters "RPT" after the station call sign if identifying by telegraphy, or the word "repeater" if identifying by telephony. Stations in auxiliary operation will be required to transmit the letters "AUX" after the station call sign if identifying by telegraphy, or the word "auxiliary if identifying by telephony. Finally, there was no opposition to our proposal to incease from five to ten minutes the minimum interval at which stations in repeater operation must identify, and we are adopting it as proposed.

d. *We are eliminating as proposed the requirement that transmissions from open access automatically controlled stations in repeater operation be either monitored in real time or recorded.* There was no opposition in the comments to our proposed relaxation. Our purpose in adopting this regulation originally was simply to ensure that licensees posses adequate means to determine whether their automatically controlled stations were being operated properly. Licensees of such stations continue to be responsible for the propef operation of their stations, but we believe we should provide amateurs with sufficient flexibility to enable them to determine compliance with our regulations in other ways. In addition, several respondents asked that the regulation be extended to exempt stations in repeater operation from third party traffic logging requirements entirely. Of course, our proposal to delete the monitoring/recording requirement had nothing whatsoever to do with third party traffic logging requirements, nor did we intend it to have. Although we do wish to relieve our licensees of unnecessary burdens, such as the monitoring/recording requirement, we do not believe at this time that stations in repeater operation should be exempt from third party traffic logging requirements. We recognize that as a practical matter many stations in repeater operation will continue to have to record their transmissions to ensure compliance with the third party traffic logging requirements. We also recognize these requirements may be a burden on certain stations in repeater operation, particularly those with telephone interconnection ("autopatch") capabilities. In our 1973 Report and Order in Docket 18803, however, amateur licensees were warned about use of autopatch equipment in violation of Section 97.114 of the rules, to facilitate the regular business affairs of any party. Since 1972, autopatch abuse has become, if anything, more widespread. The Amateur Radio Service is not now, and has never been, a common carrier, and third party traffic of all types must, under normal circumstances, constitute a very small part of amateur activity. We again warn the Amateur Service of unlawful use of telephone interconnection facilities and stress that unless voluntary compliance with our third party traffic regulations increases significantly, we may have to take action to curb the transmission of all third party traffic in the Amateur Radio Service. We are therefore eliminating the monitoring/recording requirement contained in Section 97.111(g)(2) of the rules but are retaining all existing third party traffic regulations.

e. *We are requiring that a photocopy of the remotely controlled station license be posted in a conspicuous place at the remotely controlled transmitter site and placed in the log of the station of each authorized control operator of the remotely controlled station.* We will also require that the name and telephone number of the station licensee and at least one control operator be posted in a conspicuous place at the remotely controlled transmitter location. We are aware that many licensees consider requirements of this sort to be unjustifiable burdens, but we believe it essential that there be adequate procedures to ensure that the Commission is able to contact the licensee or control operators of a remotely controlled station in the event of station malfunction. We agree with respondents, such as NARC, that in our proposal to require attachment of a durable tag containing certain information to the antenna or antenna feedline of a remotely controlled station would serve no useful purpose, and we decline to adopt it. Our proposal to require the log of a remotely controlled station to contain a list of authorized control operators was generally supported in the comments, and we are adopting it as proposed.

f. *We are making an additional one megahertz of spectrum available for repeater operation in the amateur two meter band.* It is clear from the comments that amateurs engage in a wide variety of activities and that repeater operation is but one of these activities. It is also clear that many amateurs believe their activities must be protected from possible encroachment by stations in repeater operation. For this reason, we will not adopt our proposal to make al amateur frequencies available for repeater and auxiliary operation. The pervasive opposition to our proposed relaxation convinces us that the Amateur Service is not fully prepared to assume responsibility for complete management of its own spectrum. We are therefore not allocating any additional frequencies for repeater operation or auxiliary operation below 144 MHz. Many comments, however, stated that there is a definite, immediate need for additional frequencies for repeater operation in the two meter band and above. At the suggestion of T-MARC, we are allocating an additional one megahertz of spectrum, 144.5 to 145.5 MHz, for repeater operation. We are also increasing Technician Class operator privileges to include 144.5–145.0 MHz, to permit Technician Class licensees to take advantage of the new allocation for repeater operation. We believe this additional allocation will meet the future need for frequencies in the two meter band for repeater operation, while providing adequate protection for weak signal and other activity in that frequency range. We do not agree with the ARRL that this allocation requires a new rule making proceeding. In our Notice of Proposed Rule Making in this proceeding we proposed to make the entire two meter band available for repeater operation. Our licensees were put on notice that we were actively considering additional frequencies for repeater operation in the two meter band. The claim that adequate notice has not been given that 144.5–145.5 MHz might be allocated for repeater operation cannot be supported. We are also making all amateur frequencies above 220 MHz, except 435–438 MHz, available for both repeater and auxiliary operation.[4] There was little, if any, opposition to an increase in the frequencies available for repeater operation above the two meter band, and we believe that in making all amateur frequencies above 220 MHz available for repeater and auxiliary operation we are providing amateur licensees with a great deal of flexibility while at the same time continuing to protect the "weak signal" two meter activity. We will continue to evaluate the spectrum requirements for repeater and auxiliary operation, however.

g. *We are taking no action at this time on our proposed new rule concerning priority in usage of amateur frequencies.* We may, however, take action at some time in the future if certain spectrum management problems within the amateur community are not settled by the amateurs themselves. As detailed in a recent Public Notice on this subject, we are increasingly concerned about malicious interference to, and from, certain amateur service 'monitoring nets'. If amateurs cannot solve these conflicts and others arising from competing demands for spectrum, then the Commission must consider additional regulations to resolve these matters. We are also not taking any action at this time on changing repeater ERP limits. Any action in this area will be done in a separate rulemaking proceeding.

7. Accordingly, *it is ordered*, pursuant to authority contained in Sections 4(i), 5(e), and 303 of the Communications Act of 1934, as amended, That Part 97 of the Commission's Rules is amended as set forth below effective November 4, 1977. *It is further ordered*, That all pending applications for new repeater station licenses in the Amateur Radio Service are dismissed. *It is further ordered*, That the Motion to Accept Late Filed Comments submitted by the American Radio Relay League, Incorporated is granted, and that the Motion to Accept Late Filed Reply Comments submitted by the Empire Radio Club is granted. *It is further ordered*, That to the extent RM-2664 and RM-2780 have not been granted herein, they are denied. *It is further ordered*, That this proceeding is terminated.

(Secs. 4, 5, 303, 48 Stat., as amended, 1066, 1068, 1082; 47 U.S.C. 154, 155, 303.)

FEDERAL COMMUNICATIONS COMMISSION,[5]
VINCENT J. MULLINS,
Secretary.

STATEMENT OF COMMISSIONER MARGITA E. WHITE CONCURRING IN PART AND DISSENTING IN PART

As a strong proponent of deregulation, I feel it is important that I explain why in this particular instance I find it necessary to disagree with the Commission's decision to no longer require separate licensing of repeater stations. It should be noted, however, that I do concur in the remainder of the Commission's proposals to deregulate Part 97 of the Commission's rules.

I was impressed, after reading the comments in this proceeding personally, that almost all the comments opposed the elimination of separate repeater station licenses. The Commission believes that the contentions of various repeater organisations including T-MARC, petitioner in RM-2780, that elimination of separate repeater station licenses will encourage more casual and haphazard operation are frivolous. I respectfully disagree. The elimination of separate repeater station licenses will make the voluntary coordination, frequency management, and voluntary enforcement of repeater operation much more difficult, thus increasing the probability of increasing interference—a probability recognized by several repeater associations as well as by the American Radio Relay League (ARRL).

The Commission is adopting the proposed rules to decrease the administrative burden associated with the processing and issuing of separate repeater station licenses. However, this burden which I do not view as substantial, since presently there are only approximately 3,000 authorized repeater stations and recently only about an average of two applications a day are received for repeater stations, must be weighed against the likelihood of increased Commission involvement in enforcement problems. It is quite likely that the potential enforcement problems will prove to be more costly than the savings to be gained by elimination of the separate processing of repeater station licenses. Moreover, I agree with the ARRL comment that by requiring a separate application for a repeater station license "the applicant is placed on notice that something more than the grant of a simple application is required." Comments, ARRL, p. 15. I also believe that repeater licensees have a special responsibility to serve the public interest and the requirement of a separate license places the licensee on notice and assists in keeping the licensee accountable.

Therefore, for the above reasons, I dissent.

---

[3] We do not believe separate regulations for so-called "remote base" stations are necessary or desirable at this time. As long as the auxiliary functions of such stations comply with the regulations for auxiliary operation, remote bases may be operated in the same manner as other amateur stations.

[4] Our decision to make the entire 420–450 MHz amateur band, except 435–438 MHz, available for repeater operation moots the "blanket" waiver granted by the Chief, Safety and Special Radio Services Bureau to permit fast-scan amateur television repeater operation in that band. That waiver is hereby terminated.

[5] By the Commission: Chairman Wiley concurring in the result; Commissioner Quello dissenting; Commissioner White concurring in part and dissenting in part and issuing a statement.

AMSAT

LOCAL AMATEUR RADIO OPERATOR ELECTED ARRL SECTION COMMUNICATIONS MANAGER FOR LA COUNTY

Stan S. Brokl of Sunland, known to his amateur radio colleagues as K6YYQ, has just added another laurel to his crown. He was elected Section Communications Manager for Los Angeles County for the American Radio Relay League, the largest amateur radio enthusiasts' organization. The League acts as spokesman for a large segment of the nearly a third of a million FCC-licensed amateur radio operators in the United States.

Stan is a senior engineering assistant at the Jet Propulsion Laboratory in Pasadena. He has been an amateur operator for twenty-two years. Among his earlier laurels were his presidency of the JPL Amateur Radio Club during 1976 and his handling of the transmission of the JPL Viking Lander pictures of the surface of Mars to the amateur radio world via slow scan TV. In many parts of the world, these pictures were the only ones received from the surface of Mars. He is also the vice chairman of the Los Angeles Council of Amateur Radio Clubs.

The American Radio Relay League, in addition to its activity as spokesman for the amateur radio communications community, has a variety of activities in which amateurs participate. For some of these, awards are granted, such as for working all states, or working all continents. The ARRL is also involved in emergency communications when the need arises. The activity is called Amateur Radio Emergency Service (ARES), which handles communications in emergencies such as floods, earthquakes, or other catastrophic occurrences when normal communications media fail. Radio amateur operators are equipped to provide such communications with their battery-powered and mobile radios.

In an interview, Stan was asked what his job was as SCM. He told us, "The SCM is the only elected official in the ARRL *operating* program. That is, programs involving "on-the-air" activities. He fosters communication networks, makes appointments of qualified amateurs to various communications functions, and generally provides the leadership for the section."

One of Stan's plans is to expand the ARES activity to place it in readiness for any emergency that should arise. He pointed out that ARES differs from the Radio Amateur Civil Emergency Service (RACES) in that the latter is operated locally by the LA County Sheriff's Disaster Communications Service to maintain communications in the public service area where officialdom must be in communication with its headquarters and the emergency services. On the other hand, ARES provides what Stan called "people-to-people communications."

Stanley S. Brokl K6YYQ was recently elected SCM for the ARRL LA section. He is shown here examining an OSCAR display at the JPL library. The turntable shows the four interior panels of OSCAR 7.

DECEMBER FLIGHT TEST OF AMSAT/JAMSAT SATELLITE TRANSPONDER

The Radio Amateur Satellite Corporation (AMSAT) has obtained the cooperation of a number of amateur radio clubs up and down the state of California in flying the AMSAT-OSCAR D 2-meter-to-70-centimeter (146 to 345 MHz) amateur radio satellite transponder for a test to provide amateurs throughout the state an opportunity to test their gear and to familiarize themselves with the techniques and procedures to be used in operating the transponder during its orbital phase as AMSAT-OSCAR 8, mode J. The flight will take place December 3, 1977. An aircraft containing the transponder will fly a course starting from Van Nuys Airport near Los Angeles to San Diego, Santa Barbara, San Francisco, Stockton, Fresno, Bakersfield, and back to Van Nuys.

This will be the fourth flight test of an amateur radio communications satellite transponder since the AMSAT-OSCAR 6 2-meter-to-10-meter was flown on the east coast in May, 1971, by members of the AMSAT Washington group. In September, 1971, the Jet Propulsion Laboratory Amateur Radio Club ran a flight test similar to the one to be run in December on the 2-to-10-meter transponder. JPL ARC was also involved in a flight test of the 432.15 MHz to 145.95 MHz "Umsetzer" (built by AMSAT Deutschland) which became the mode B transponder of OSCAR 7. The latter flight test was run in September, 1973.

A great many amateur operators participated in these earlier flight tests, learning the ropes, so to speak, about operating through an amateur satellite transponder under closely similar conditions to those which would occur in orbit.

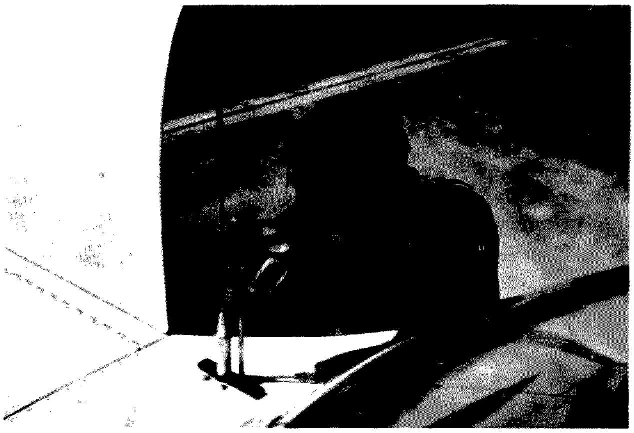
Activity through the transponder is encouraged during the December 3rd flight, and a commemorative QSL will be sent to all amateurs who send in a report of stations worked or heard. The aircraft call in flight will be WA3NDS.

During the flight, a liaison net will be maintained at about 7230 kHz, using the call W6VIO.

The test flight is cosponsored by the amateur radio clubs of Jet Propulsion Laboratory, Hughes, TRW, and Project OSCAR, as well as several other California amateur organizations.

One major purpose of the flight is to assist radio amateurs in adjusting their equipment for operation on the new amateur satellite frequencies above 435 MHz, the only available frequencies in the 420-450 MHz band open to satellite use under the ITU regulations. A secondary purpose is to determine the mutual interference potential between AMSAT-OSCAR D and amateur TV enthusiasts operating above 435 MHz. Launch of the AO-D amateur radio communications satellite is scheduled for February 17, 1978.

Reports should be sent to Skip Reymann W6PAJ, at Post Office Box 374, San Dimas, California 91773.



Dick Ulrich K6KCY puts finishing touches on the 10 meter whip for the OSCAR 7 test flight in 1973. Dick will participate in the flight test of the AMSAT/JAMSAT spacecraft in December.

LETTERS

from page 17

GE and various doctors would not give me any suggestions, I was lucky enough to get in touch with a man in the School of Aerospace Medicine, who told me of their extensive experiments with electromagnetic radiation and pacemakers, including 15 models of the GE, which proved them particularly susceptible. It is true that their experiments were not on a ham frequency, but their frequency was near enough the 20 meter band to be *significant.* It was *here* that I got suggestions for the grounded cage I built.

Possibly you may have occasion to pass along my experiences, or to improve upon them.

F. L. Wiltrout W9VFG

Newington CT 06111

Dear Sir:

Some time ago, I wrote you that I had a General Electric pacemaker installed, and that when I attempted to make a transmission the radiation cut it out. I asked if you knew of any articles in ham publications or otherwise which might help me get on the air. Your reply was negative.

I have since read newspaper articles to the effect that CBers, using illegal amplifiers, were interfering not only with pacemakers, but also with hearing aids.

I solved the problem in a somewhat awkward manner, and I would like to pass along my experiences, thinking that they would be a basis for further refinement.

To begin with, I use a Drake TR-4 and a Heathkit SB230 linear, feeding an old Hy-Gain 20, 15, and 10 meter beam with coax. I have a switch arrangement to go from the beam to a Heathkit dummy load.

Using an inexpensive field strength meter, with the aid of my son (who is also a ham), I found that the field strength varied according to which way the beam was headed — that even on the ground forty feet from the beam, with the beam headed in my direction, the pacemaker acted up. I could tell when the rig was on transmit merely by feeling my pulse.

The next step was to take readings when the rig was on the dummy load. There was no reading whatsoever even when the meter was set on top of the rig. (Incidentally, the swr is down to one to one.)

My son and I then constructed a sort of cage, five feet high and three feet wide and deep, with both top and bottom, of perforated aluminum sheet, covered by a layer of copper wire. This was attached to a good outside ground. The microphone with switch was run into the cage, and I was back on the air! There was no field strength reading in the cage while transmitting. It is a little awkward reaching out the door to tune in stations, but you can't have everything. The rig itself can be tuned up on the dummy load.

So far I have tried only 20 and 40 meters, the latter on an inverted V, without the linear.

This is the old principle of the Faraday Cage, discovered in England many years ago, and hardly mentioned in the *Handbook.*

It occurs to me that the transceiver itself could be moved into the cage for greater operating convenience.

You can understand why I am reluctant to do too much experimenting personally when it might stop my heart.

Perhaps a more simple solution could be found, like putting some kind of shield on the roof underneath the beam, or on the ceiling of the shack.

Anyway, perhaps one of your bright young men might be willing to take my experiments and build on them. They are welcome to use my observations and experience.

SUPER PAT

Although in the past I've not been in entire agreement with most of your editorials, I will say this much — I've written several letters praising your study guides (which you've never printed). Well, here comes a super pat on your back with a request following.

On August 29, 1977, my employment required that I obtain a 2nd Class Radiotelegraph license. The first thought in my head was, "Oh-oh, a supervised code exam at 20 and 16 wpm," so I got out your 20+ tape — the one with all the weird characters — and listened to it for ½ hour every day for 17 days. (Keep in mind that I've been inactive for 3 years now.) Come the 29th in Detroit, the examiner put 20 wpm on and I really was shocked — it sounded like about 15 wpm! I swear I could have sharpened my pencil in between groups. No kidding! I even copied 35 wpm almost solid after listening to that tape — the same tape that, by the way, at first I spent 10 minutes of each half hour cursing. I now have a 2nd Class Radiotelephone, a 2nd Class Radiotelegraph, and an Advanced ham license, which I can say were duck soup to get after using your study guides and tapes. Now I will be going to Marquette to take the First Class Radiotelephone, the Extra Class, and the Radar Endorsement.

By the way, I'll be going for my 1st Class Radiotelegraph in a few months — do you have a 25+ wpm tape I can purchase?

Kenneth M. Cubilo, Jr. WB8DOI
Rogers City MI

Sure, $4.00. — Ed.

BE A LEGAL JAMMER

We would like to invite a couple of hams around the world for communication backup, and they can take all their equipment. We would give them 1/3 off the total cruise cost.

Captain Mike Burke
Windjammer Cruises
PO Box 120
Miami Beach FL 33139

FEATHER

Just wanted to drop you a note and put another feather in your cap. Last June, I purchased your 21+ wpm tape. When I received it, I played it for about five minutes. I then ignored the tape until the first of September. I practiced your tape an average of 45 minutes a day for 3 weeks. On September 21, I went to the FCC and took the exam. I aced the code test. I didn't have time to sleep in between characters, but I did copy comfortably the 20 wpm. I could copy your tape about 98% — let's face it, a code group like "kee ie" is something else. If you can't copy the group, it does teach you not to be flustered by missing a character or small group of characters.

Once again, thanks — and be proud of those feathers and cap. I will be forwarding my callsign change when I get my 2x2 call.

M.O.M.

With Christmas again rapidly approaching, we at Military Overseas Mail are concerned about the many thousands of our military personnel who will be away from their homes and families during the holiday season. For many of these young men and women, this will be the first Christmas away from home.

Readers of *73 Magazine* can help make this holiday season a little less lonely and a little more enjoyable for many of these young people by joining in the collection of Christmas mail sponsored by Military Overseas Mail. This is an ideal project for school classes, clubs, and other groups as well as individuals and families. For more information, please send an SASE to Military Overseas Mail, Box 4330, Arlington VA 22204, and mention that you read about M.O.M. in *73 Magazine.* Thank you.

Lee Spencer

Compare the Atlas 350-XL with other transceivers . . .

TYPE	ALL SOLID STATE			HYBRID (VACUUM TUBE P.A.)			
MODEL	ATLAS 350-XL	TEN TEC	YAESU FT-301	DRAKE TR4-CW	HY-GAIN 3750	KENWOOD TS-820	TEMPO 2020
INPUT POWER	350 WATTS	200	200	300	200	200	180
BANDS	10-160M	10-80M 160M OPT	10-160M	10-80M	10-160M	10-160M	10-80M

. . . and see why it's your best buy!

Above is a chart comparing leading HF Transceivers that fall in approximately the same price range as the Atlas 350-XL. The Drake TR4-CW is least expensive, while the HY-Gain 3750 is the highest. Rated power input (SSB) and bands covered are listed in the chart, but below is a discussion on a number of other interesting comparisons which will help you choose the right transceiver for your station.

1. STATE-OF-THE-ART, ALL SOLID STATE

The first 3 transceivers listed above are all solid state. The real designs of the future! Having manufactured and sold over 12,000 of our little 210x/215x's, we can attest to the high performance and reliability of all solid state design. Tubes for the driver and P.A., with their tuning circuits and high voltage power supplies are rapidly becoming obsolete. As a result their resale value will be declining.

2.POWER RATING.

The higher power rating on the 350-XL provides you with a comfortable edge over the others. Running barefoot you can easily ride over the competition. If you're driving a linear you don't have to strain for every bit of drive from the transceiver. It can loaf along with ease. The 350 watt input rating is really very conservative. Typical input power runs upwards of 400 to 450 watts without flat-topping. Considerably more than the others.

3. BAND COVERAGE

Not only does the 350-XL cover the 10 through 160 meter bands (including all of 10 meters in four 500 kHz segments), but one of its exclusive features is that you can install up to 10 auxiliary 500 kHz ranges anywhere from 2 to 5 MHz, and from 6 to 23 MHz. This gives you great flexibility for MARS operation and possible future amateur bands. Crystals for Auxiliary Ranges are installed internally. In addition, the 350-XL provides reception of WWV at 5, 10, and 15 MHz, without having to add any auxiliary range crystals.

4. DIGITAL FREQUENCY READOUT

On the 350-XL, the optional Digital Dial can be installed, and you still retain the conventional analog dial, with the option of switching the digital dial off if you wish. With the Ten-Tec or Yaesu 301, you lose the analog dial if you purchase the digital dial model, making you totally dependent on the digital dial.

5. FULL BREAK-IN CW

Only two rigs offer this feature; the Atlas 350-XL and the Ten-Tec ! The others are all "semi-break-in". And the Atlas includes CW sidetone with pitch and volume adjustments.

6. NARROW BAND CW FILTER

This is another standard feature in the Atlas, optional on the Ten-Tec , Yaesu, and Kenwood. Ours is an I.F. filter with 500 Hz bandwidth, and shape factor of better than 3 to 1.

7. A.F. NOTCH FILTER

This 350-XL standard feature permits nulling out heterodynes and other interference. The Yaesu, Hy-Gain and Kenwood include a similar feature.

8.SPEECH COMPRESSION

The standard Atlas ALC system provides up to 20 dB of R.F. compression which increases your talk power and at the same time reduces "flat-topping" and splatter. An optional speech processor to provide up to 20 dB additional A.F. compression will be available soon for installation in the AC supply. The Hy-Gain, Kenwood, and Yaesu also provide some form of speech processing.

9. AUXILIARY VFO

All of the rigs listed offer an optional second VFO for split frequency operation. But Atlas is the only one with an Auxiliary VFO that is not an add-on box. The Atlas Auxiliary VFO plugs right into a space provided in the upper right hand corner of the front panel. Although miniature in size it tunes the same 500 kHz as the primary VFO, and does it smoothly with coarse and fine controls that have 10:1 planetary drives. Green, yellow, and red LEO's let you know which VFO you have set up for receiving and transmitting. Very neat, and all self-contained.

An option to the Model 305 Auxiliary VFO is the Model 311 crystal oscillator that provides up to 12 crystal controlled channels. It also plugs into the front panel just like the 305. Vernier controls provide fine tuning of the crystal frequency.

10. MOBILE/PORTABLE OPERATION

The Atlas, Ten-Tec , and Yaesu, being solid state, are unique in that they will operate mobile or portable directly from a 12-14 volt DC battery. Also, the solid state rigs are considerably smaller and lighter weight than the hybrid rigs. The Atlas is unique in having a very handy plug-in mobile bracket for the 350-XL that makes it a simple matter to plug-in and go mobile.

11. OTHER 350-XL STANDARD

FEATURES include R.I.T., VOX, Crystal Calibration, ANL, and Noise Blanker.

Compare the Atlas 350-XL SSB-CW Transceiver with the others, and we think you'll agrea the Atlas has everything you'll ever need in a transceiver. And it's made in America.

And let us not forget to mention Our Customer Service which is second to none. Just ask the ham who owns one.

Model 350-XL (less options) . . . $995.
Model DD6-XL Digital Dial . . . . $229.
Model 305 Auxiliary VFO . . . . . $155.

MADE IN AMERICA

We're very proud that every Atlas transceiver is made right here in America, (as are the Ten-Tec and Drake). We think the American worker, and eur employees in particular, are the mast talented, industrious people in the world. The quality and versatility of our transceivers are proof of this.

And by using this American quality workmanship, advanced value engineering in design and manufacture, and rigid quality control, the Atlas transceiver is not only competitively priced with the imports, but is actually a better value!

Merry Christmas and Holiday Greetings from all the gang at Atlas!

Inside Ten-Tec
-- QRP innovators

It started with a telephone call in 1969. Al Kahn, former president of Electro-Voice, rang up Jack Burchfield, a design engineer for Bogan in New Jersey. Kahn had moved from Michigan to Sevierville, Tennessee, after he left Electro-Voice, and he wanted to get back into the mainstream.

Dick Frey K4XU/W1FCC is Ten-Tec's chief engineer. The Century 21 is his design, and he's obviously proud of it. "It works great on the bands," Dick beams, and says he's finally doing the job he's always wanted to do. That seems to be the spirit throughout the Ten-Tec operation.

"Hey, Jack, come on down, and let's do something," he suggested in that first telephone call. To hear Jack Burchfield tell it, a second request wasn't needed. He had so much confidence in the man he had worked with when he himself was at E-V, that Jack immediately packed up his family and moved south to Tennessee.

Both admit that Ten-Tec, Incorporated, a company now well-known for its solid state ham gear, wasn't formed in the conventional manner. Once they got together in Sevierville, the pair set about adding some kind of manufacturing business to their tool and die shop already under construction. Hi-fi gear came to mind first, since both had a number of years of experience in the field.

Al says they rejected that idea pretty quickly because, "We both were sort of tired of it. After the pioneering days were over, the fun went

out of it." They agreed, instead, that they should pioneer some form of amateur radio equipment for the beginner. And the Power Mite line of solid state transmitter and receiver modules was born.

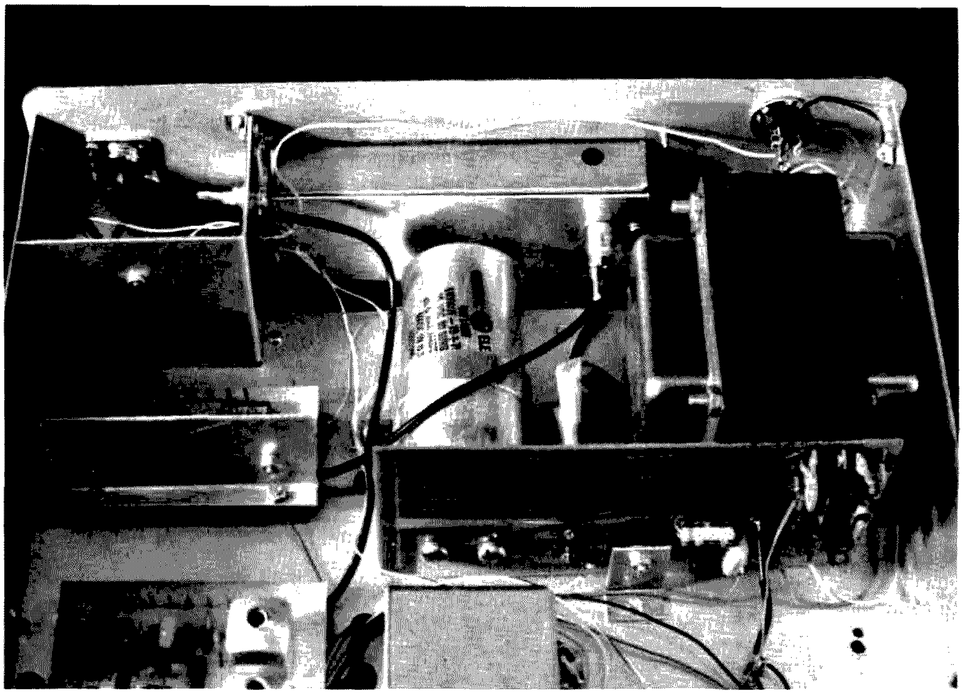
Low-power, low-priced solid state kits for the amateur market was an idea whose time just hadn't come, however. Ten-Tec sold fewer than five thousand of the units, and the ones they did sell went not to the beginner but to the guy with the S-line and the two letter call.

"If a Novice is going to work anybody with two Watts, he'd better have everything just about perfect," Jack said. "So most of the equipment went to the ham who wanted the challenge and to the QRP group."

Whatever the reason, sales volumes weren't high enough to support the young company, even though the multi-thousand square foot plant was paid for before production started. There were two founding principles they weren't ready to give up, though: low power and solid state design. The Argonaut was the next logical step, and acceptance was a little more general, even though it still ran only five Watts. This was in 1971. There were four more years of slim times before this guts-formed company became a force large enough to be reckoned with in the ham radio market.

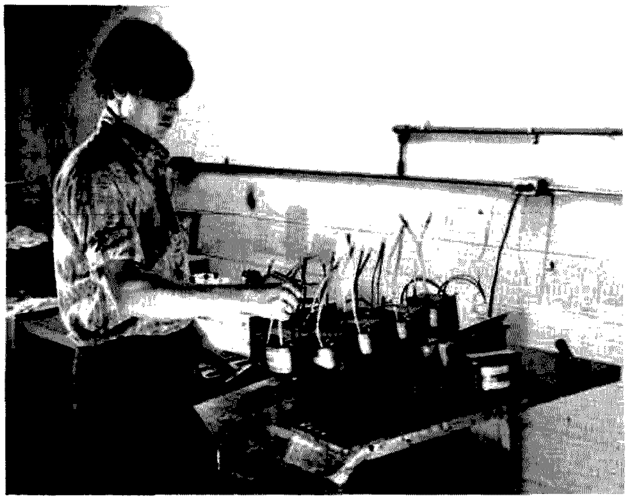
"We're making money now," board chairman Kahn says. "We turned the corner with the Triton."

One reason for the slow financial success may have been the company's strict dedication to treating the ham fairly. After the Triton came out, for example, it was decided that some design changes should be made. But before marketing the new unit, Ten-Tec made sure all the dealers knew a new design was on the way, and they instructed their dealers to tell Triton purchasers a new box was coming.

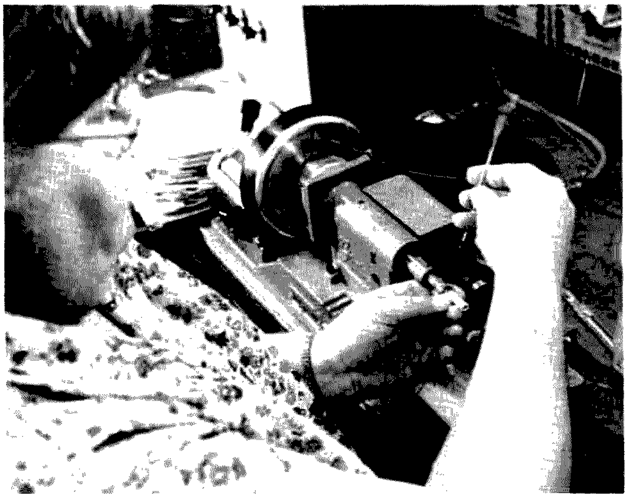


Reminiscent of Ten-Tec's earliest beginnings, this latest design — a solid state CW transceiver — began with a telephone call. Ten-Tec founder Al Kahn K4FW says he got three calls in quick succession from people wanting a reasonably priced station for large Novice classes. The Century 21 was the result — all solid state, broadband tuning, 70 Watts input, direct conversion receiver. Complete with built-in power supply, the unit is selling for $289.00. This is a prototype, but it's all there. Nothing is missing, even though there seems to be lots of room left over inside.

Ten-Tec President Jack Burchfield K5JU (left, standing) and Board Chairman Al Kahn K4FW (right, standing) watch as a technician gives one of the new digital Triton IVs an on-the-air check.



Even the power transformers for Ten-Tec equipment are wound at the Sevierville TN plant. A machine automatically inserts laminations in the transformer windings, then the whole affair is dipped in a sealant and put on a rack to harden.



This coil winder is a Ten-Tec innovation. The machine is attached to a digital turns-counter, which also is programmed to stop the winder after the proper number of turns has been applied to the form. It saves time and cuts down on errors.

The familiar red and black Ten-Tec logo ready to go on a Triton IV, or Argonaut, or keyer, or Century 21, or power supply, or . . .

"It probably cost us $25,000 to $30,000 to do it that way," Al says, "but we did it knowingly and it was the right move."

Design standards are strict, too. Until recently, Jack Burchfield was chief engineer as well as company president, and, with ten or fifteen years in the audio business, he naturally put some of that experience into the Triton – less than two per cent audio distortion, for example. Too, he says, computer predictions show a useful life on the solid state finals of 25 years. (In thousands of Tritons shipped, only 5 final transistors have failed.) Each vfo board is individually compensated for temperature stability after it is built. Toroids, coils, cabinets, chassis, circuit boards, dial mechanisms, transformers – they're all built under one roof in Sevierville, Tennessee.

What's the ham market like today? Challenging, Jack and Al agree, and changing. A ham doesn't have to be an engineer anymore to have functional equipment, and, Jack believes, more and more people are getting into ham radio "to talk to people, not to tinker." That's one reason Ten-Tec is offering sophisticated gear that's easy to operate – broadband tuning, for example, and instant break-in.

Supplying the ham market is a little like trying to please all the people all the time. It means keeping up with changing technology, but, moreover, staying abreast with what the buyer wants. To that end, a digital readout version of the Triton IV already is moving down the production line. Right behind it is a solid state, CW-only transceiver, which eventually will grow into a complete station package – keyer, tuner, antenna. A kilowatt solid state linear is on the back burner.

The Ten-Tec company presents an unusual dichotomy – state-of-the-art hardware and old-fashioned philosophy. Even though starting with all solid state equipment probably slowed the company's development, Al and Jack are adamant that whatever they design will use no tubes. They're putting those modern circuit designs in almost futuristic enclosures.

They work hard, on the other hand, to maintain a small-company, personal approach to the business as they grow. Even with $3 million in sales projected next year, there seems to be no worry about the company losing its personality.

"We did it at Electro-Voice," Al reflects. "It's just got to start at the top and go down."

Wherever it starts, the feeling is there. The people throughout the plant obviously take pride in their work. They're proud of the Ten-Tec equipment they're turning out. They seem to know a great deal about the work they perform, and there's a comradeship among all the staff that's heartening in these days when most people seem reticent in their relationships.

It's encouraging, too, to hear a ham equipment supplier promise to supply state-of-the-art gear based on a good engineering design, maintain a five-year warranty on the product, and answer every query and comment on the equipment.

Ham radio is growing and so are most companies supplying these new hobbyists. The hams at Ten-Tec have a move-carefully attitude – partly because they're not sure what direction ham radio may take in the future. But Al Kahn is sure of one thing: "Whatever you're doing, do it the best you can, and don't try to move into greener pastures until you can nail down your present job."

That idea pervades the Sevierville plant. It's as if everybody is walking around with a mouthful of nails and a big hammer. ■

The History of Ham Radio

-- part V

Reprinted from QCC News, a publication of the Chicago Area Chapter of the QCWA.

The first amateur radio get-together of any size was the St. Louis Midwest Convention in December of 1920, shortly after our licenses became available in 1919. No sooner had the enthusiasm at the St. Louis gathering died down, than the ARRL Board of Directors proposed a national convention.

In these early years after World War I, there was so much newness in everything connected with wireless, and there were so many original and worthwhile ideas to be aired, that no mere Morse code contact was sufficient. Voice communication had not as yet entered our amateur wireless channels. Amateurs were on the verge of many new developments. Major Armstrong had announced his "single" signal regenerative and then his superregenerative receiver designs. There were new circuits to be tested in the transmitter field, including the Colpitts, the Meissner, the Hartley, and the Heising, among others.

Amateurs wanted to be informed. They found themselves in new technical surroundings. So, for the first time, citizens of the United States and Canada, all interested in privately-owned and operated radio communication, decided to come together from far and near to a big first national convention.

The first gathering of the clan took place from August 30 to September 3, 1921, at the Edgewater Beach Hotel, located on the shore of Lake Michigan in Illinois. History relates that, following the success achieved at this first national convention, it was ordained that two succeeding ARRL national conventions were also to be held at the Edgewater Beach Hotel in Chicago at two year intervals – September 11 to 15, 1923, and August 18 to 23, 1925.

There was no telling what impact these get-togethers would have on the future destiny of amateur radio. Great effort and meticulous preparations were made for months in advance to insure success. Everyone connected with the preparations hoped that this first national meeting would find attendance coming from the far reaches of the States and Dominion, representing all districts.

The midwest location proved to be a most stragetic and advantageous choice. The Edgewater Beach Hotel was at the far north edge of Chicago, away from heavy traffic, with R.H.G. Mathews' 9ZN station located just to the north on the lake shore, spurting two tall station towers, a multiwire antenna, and up-to-date equipment in his spacious shack. All agreed that this was an ideal spot to congregate.

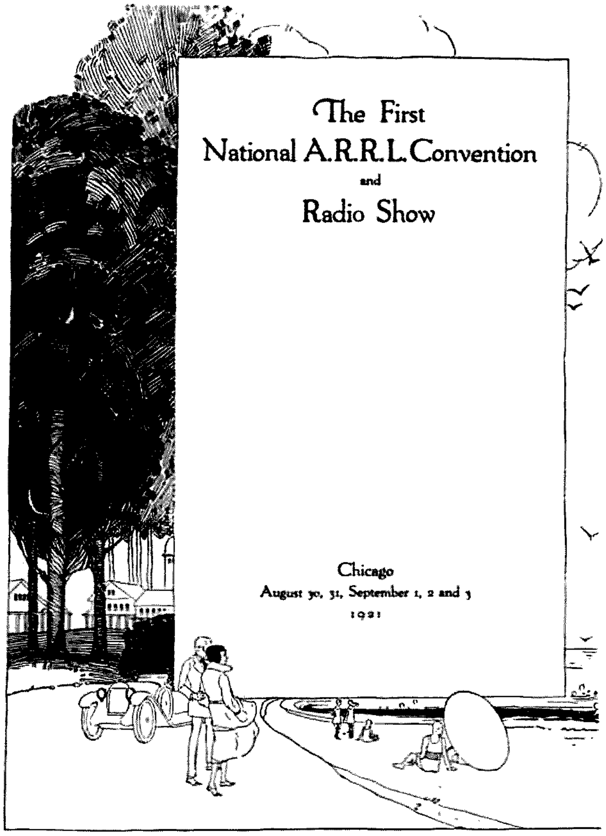
The convention committee had booked a large arena, the Chicago Broadway Armory, located within walking distance of the hotel. About fifty manufacturers and dealers in ham radio gear of all description displayed and demonstrated their products. For the first time, amateurs had an opportunity to talk shop with those people who had kept amateur radio alive through their advertising in *QST*, *Radio Amateur News*, *Wireless Age*, catalogues, and other literature. This was a ham's paradise!

The convention hall, where all the sessions took place, was a beehive of activity. There was no letup in making personal contacts, exchanging QSLs, and discussing many subjects slated on the agenda.

The First Day

The ARRL President, Hiram Percy Maxim, addressed the members with an inspiring talk concerning the aims and accomplishments which amateur radio had achieved in the relatively few years of the ARRL's organization. In his introductory remarks, the founder of the League had the following to say:

"As we meet and open this great convention, it is indeed



The Convention

THRU the many years of amateur radio there has developed an increasing desire to meet the other fellows that are, like yourself, interested in radio communication either as a pastime or business. And now comes a time when your wishes shall be gratified.

For, in Chicago on August 30, 31, September 1, 2 and 3, 1921, the American Radio Relay League will hold a First National Convention and Radio Show, which everyone is cordially invited to attend.

Chicago is itself a wonderful summer resort, offering every opportunity in any sport or diversion. You will never regret having spent part of your vacation here. The details of the convention are exceedingly comprehensive and every minute of the convention will be taken up with interesting and educational conference and lectures, being in all a most complete and co-ordinated program. Mornings, afternoons and evenings are fully arranged for, so that you will remember this convention as some of the most enjoyable days of your life.

There will be people that you know and many that you do not know that will be present from every district and city in this great United States. Probably the most important feature of the convention will be the huge banquet on the night of September 3rd, and there should be none failing to attend. Everybody from the Young Squirt up to President Harding will be there to pass you the sugar and tell you what a record station he or she is going to have this season.

The first day will be given over entirely to the arrival, registration and locating of the many delegates. The program will start promptly at ten A. M. August 31st, so you should arrange to be in Chicago some time during the previous day, August 30th.

We have arranged to accommodate you at the finest hotels in the city, very close to all activities, at rates from two dollars per day up.

From the moment that each delegate arrives, and they should not forget to bring the ladies, until their departure, the utmost of consideration will be devoted to their safety, comfort and pleasure.

Convention delegates will be admitted to the meetings, lectures, sportive expeditions and the Radio Show without any charge.

Banquet charges will be five dollars per plate, and reservations should be made immediately with convention reservation manager,

N. C. BOS
118 No. LaSalle Street
Chicago, Illinois

(Make all remittances payable to Chicago Executive Radio Council)

The Radio Show

THE manufacturers and dealers' exhibit at the First National Radio Show, which is to be held in conjunction with the convention, will be the most spectacular conglomeration of modern radio equipment that has ever been put on display under one roof. This gorgeous and pompous affair will be well worth the trip itself.

The Broadway Armory, the most modern and largest exhibit and convention building in Chicago, will be used entirely for this great show.

Divided into model exhibit booths and beautifully decorated in one accord, it will equal in splendor any of the successful automobile shows. The magnitude of the affair is positively stupendous.

It will indeed be a great thing for the manufacturer and dealer, as it is held at a time that marks the opening of a new and more active radio season. Business conditions are rapidly improving and a very successful season is predicted.

In addition to publicity thru radio publications, circulars and placards, the daily newspapers with circulation over the million mark will be employed to advertise the show. This should result in a daily attendance of anywhere from three to eight thousand of interested people. The results to the advertisers, both direct and indirect, will be unprecedented.

This is not a money making proposition and the booths are being sold on approximately a pro-rata basis. The convention delegates will be admitted without charge, and the general public will pay an admission fee. Permanent passes will be issued to exhibitors. The show will open at the same time as the convention, ten A. M. August 31st, and everything must be in readiness the day before.

Here are some reasons why every manufacturer and dealer should be an exhibitor: It is the biggest affair that has ever been promoted in the age of radio. It comes at a time that marks the opening of the regular radio season. There will probably be over ten thousand people reviewing the apparatus. By personal contact with the field which he is selling he may gain good will. The exhibit cost is low and the results will be big.

Your competitor may have an exhibit and if you do not—well, think it over.

There will be every accommodation available for the exhibitor, delegates and the general public. The Armory is conveniently located near the three hotels at which the majority of the delegates will stop. There are also excellent amateur stations near by which will supply both spark and phone transmission for the reception of exhibitors.

It will be a long while before such opportunities as are here offered will again be presented.

a historic event . . . In years to come, much will be said about what we do here at this first convention. We are striking out into the unknown, and even the smaller actions which we take here during the next few days will weigh heavily in the future, for they will establish precedents and standards . . . Let us not forget that we are pioneers, blazing a way many are to follow. Our responsibility is great, and we must so regard it. It is one thing to repeat what has already been done, but it is another altogether different thing to do what has never been done before. What you see before you here today has never happened in the affairs of man. Not only is it a great pioneer effort in radio history, but it is a great pioneer effort in political history. We American and Canadian citizens assembled in this room represent pioneers in the development of something totally revolutionary in the art of communication. The like of what we are doing and proposing had never crossed the brain of man a short ten years ago. We already have a privately-owned, absolutely free continentwide means of instantaneous communication and no man may say we shall not make it worldwide." (What prophetic statements emerged from this gathering of dedicated and enthusiastic men!)

"It is no small distinction," our President went on to say, "to be one of those who make history."

General and Technical Sessions

There would be no point in listing the names of the high and low notables in attendance. They were all present. The program committee had topics scheduled for discussion pertaining to club organization, interference control, observations of laws, legislative matters, message handling, and many technical subjects.

Charles H. Steward, member of the ARRL legislative committee, reviewed pending legislation, a matter which required constant attention. Seven bills under debate in Congress at that particular time related to sub-

jects concerning radio control, radio regulation, and enforcement. Observations made at this meeting were that: "If just two of these bills go through in their present form, the wavelengths, power, and decrement are then subject to control of the Commission, and they keep us champing around from one wavelength to another, increasing and decreasing the power available for amateurs. Constant vigilance is of vital importance to insure the amateur's place in the radio spectrum."

Probably the topic which drew top attention during the convention, and which was subject to heightened debate, proved to be the controversial question of power factor in ham transmitter circuits. As one reporter remarked afterward, "Without a doubt, this debate was the main attraction at the convention."

There were staunch supporters of the two main participants in the discussion, and it did not take long before sides were chosen. At the outset, Ellery W. Stone from the west and W. B. West 8AEZ were the antagonists in this struggle for definition and thoroughness of detail for presentation of facts.

Said Mr. Stone: "Power factor is unity in any ac circuit in which inductive and capacitive reactances cancel."

Said Mr. West (ignoring inductance and capacitance): "I confine my views in the matter to the relation of real Watts to apparent Watts."

This confrontation went on for hours, with other participants joining, until all agreed that it appeared that the confusion lay in the definition of power factor. There was no common understanding reached by the two parties. So it was decided, on the spot, to submit the question to the radio section of the Bureau of Standards, Washington, D.C. The statement submitted to the Bureau read as follows:

"For information of National Convention of ARRL, please wire our expense immediately: In a freely oscillating radio circuit, and in a forced oscillating circuit tuned to resonance with the impressed frequency, if the inductive and capacitive reactances are equal in magnitude and opposite in sense, is the power factor unity? One side contends that, according to present alternating current theory, the power factor is unity, and reactances are equal and opposite. Other side contends that resonance is that condition in circuit which causes power factor to automatically assume that degree necessary for the complete dissipation of the power applied to the circuit."

Within hours after the telegram was forwarded to the Bureau, the reply came back . . . with the answer which, in essence, left both sides very much up in the air. Supporters of both Mr. West and Mr. Stone hailed the outcome of the reply as complete vindication of their respective sides. Even a committee thereupon appointed to review the entire discussion finally ended up by stating that they are not reasoning from the same premise. Most of those in attendance finally concluded by these vague decisions that another subject could be more productive and down to earth and headed for other meetings.

Of great interest to ama-

QST January, 19..

RADIO 9ZN

Radio 9ZN, the station of the Central Division Manager, is located at 5525 Sheridan Road, Chicago, Ill., on the shore of Lake Michigan.

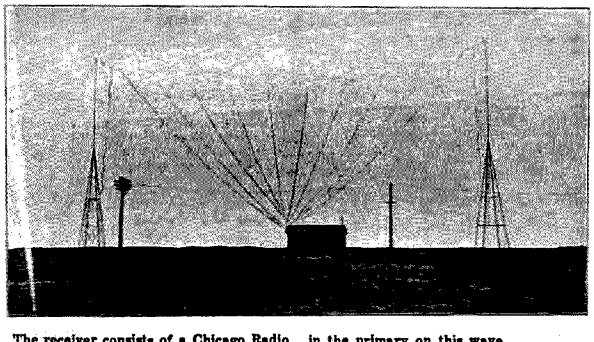
The station consists of a two room, one story frame building situated midway between the two towers supporting the antenna. The building, towers and plane of the antenna are in a north-and-south line, at a distance of 60 feet from the edge of the lake. Because of this location, the station is clear of practically all high buildings and obstructions in all directions.

The aerial is 95 feet high, over all, the towers being of steel, 50 feet high, and the masts being also of steel, 45 feet in height. The towers are 150 feet apart, the ten wires composing the antenna being spaced equally within this distance, in the well-known vertical fan fashion. The aerial wires are 7 strand No. 22 tinned copper wire, the top cable being 7 strand No. 18 phosphor bronze, with three 10½ inch Electrose insulators at each end. The loose end wire attached to the tower sides of the insulators are to provide downhauls for the cable should the serial give way.

The ground system of the station is perhaps one of the principal reasons for its success. It is composed of two banks of wires, one consisting of 20 wires (No. 14 bare copper) each 30 feet long, buried radially from the station, and the other consisting of 8 wires (7 strand No. 22 copper) each 150 feet long, buried similarly. In addition, two wires, each 100 feet long are submerged in the lake, and a number of 6 foot rods are driven into the ground about the station.

Power is provided by a 4 K.W. special power line, shown in the illustration. Telephone is also provided, the number being Sunnyside 10153.

Hy-Rad rotary gap. The rotary gap is contained within a double walled padded box, just behind the marble panel, on which are mounted the radiation ammeter, power variation switch, power ammeter and main switch, the transformer being directly beneath the gap box. The oil condenser is immediately to the right of the switchboard, and consists of 1200 square inches of tinfoil separated by ⅜ inch plate glass immersed in transformer oil. The oscillation transformer is made of 1" x 1/16" brass ribbon and is mounted as shown. The full condenser is used for the 425 meter wave, but only a part is used on 200 meters, the amount being such that only one turn of inductance is used



The receiver consists of a Chicago Radio Laboratory Paragon RA-6 short wave regenerative receiver and Amplifigon type AGN-2 audion control and two step amplifier. An Audiotron tube is used for detector, Western Electric VT-1's or Marconi VT's being used as amplifiers. With this receiver are used Baldwin Mica Diaphragm headphones. Practically all the long distance amateur stations are heard with the phones on the table on average nights; many, such as 2CS, 2ZS, 5AF, 8AA, 8ER, 9BT, 9BR, etc., being generally heard at distances up to 100 feet from the headphones. Six hundred meter stations are heard similarly. At present no set is provided for longer waves than 600 meters, but an undamped wave receiver is under construction.

The transmitter consists of a Marconi (United W.T.Co.,) open core 1 K.W. transformer, having a secondary voltage of 30,000, with an oil immersed plate glass condenser, and a Chicago Radio Laboratory in the primary on this wave.

Because of the high fundamental wave length of the aerial (300 meters) all 200 meter transmission and reception are done through series condensers, the transmitting series condenser consisting of 175 square inches of tin foil separated by ⅜" plate glass and immersed in oil. This condenser is located just above the loader, which is used for 425 and 600 meter waves.

The radiation on 200 meters is 8¾ amperes, and on 425 meters is 9 amperes, the 425 being really better than would appear from a direct comparison of these readings, because of the elimination of the series condenser, and also because of the greater carrying ability of this wave.

The 200 meter wave is used ordinarily, with a shift to 425 to avoid interference or to work over greater than average distances. The answering wave of this station is invariably 200 meters, unless otherwise specified by the calling station.

(Concluded on page 35)

teurs who were still purchasing and installing spark gap transmitters was the subject of broadband interference. It was contended that spark gap units were doomed to fade out of ham stations, because the waves they transmitted on the air were not as sharp as a CW wave. It is true that they could be held better in reception and did not have tendencies to jam each other, like the CW signals did. Also, each spark on the band had an individual characteristic that identified it, and what distances could be covered (having 1000 Watts available)! The overall sensitivity and selectivity of circuits was a hindrance. The CW signals were difficult to tune and hold. Wave shifting was usually noticeable. Regenerative receivers had shortcomings, especially since they were asked to be equally effective in bringing in CW, ICW, and the broad spark signals. Receivers lacked adequate control to meet requirements. Being regenerative, they radiated energy and caused considerable interference, especially in more congested areas.

Operator, 9ZN.

For most signal reception, the oversized loose couplers in station equipment were still serving their major purpose. Domestic and foreign longwave stations were very much on the air with news broadcasts, weather reports, time signals, and general information. Many stations served as sources of code signals for practice — NAA, 2,500 meters; POZ, 12,000 meters; PL, 10,000 meters; and MUU, 14,000 meters, continued on the air for years.

So loose couplers were in constant use by amateurs until, with the introduction of the honeycomb-coil design, units which occupied far less space but had equivalent inductance gradually replaced them. Amateurs also began to convert to shorter and shorter wavelengths with the move to CW and the application of available transmitting tubes. Amateur station layouts began to take on new and revitalized appearances. Power supplies had to be designed and built to accommodate larger tubes for that new requirement of "juice" for the "bottles." In turn, many new receivers were being built using variometers and variocouplers.

As is the case each year, with the coming of fall and colder weather, radio conditions improved, static tapered off, and interest in DX and relay activities increased. So the ARRL Board of Directors decided that a determined effort should be made to span the Atlantic via amateur radio. There had been an earlier try, not organized, that had failed. Undaunted, plans were laid by the ARRL traffic department announcing that all radio amateurs should enter into a series of transmitter tests. Selections would be made to find the best and most far-reaching transmitters to qualify for the proposed undertaking. The following form appeared in *QST*, September, 1921, page 12, directed to all hams:

"Traffic Manager, ARRL, 1045 Main Street, Hartford CT.: Please enter my station as a transmitter in the Trans-atlantic Sending Tests, Dec. 8th to 17th. I will be ready to transmit in the preliminary tests on Nov. 7th to 12th, and if I fail to cover the specified distance in the preliminary tests, I shall relinquish my rights to transmit in the final tests. Name . . . Call . . . St . . . City . . . State . . . Power of transmitter . . . type (CW or spark) . . . greatest distance heard (give three records) . . ."

The stated goal was: "We want the Atlantic Ocean spanned on schedule by an amateur station, and we want definite proof that it has been done." ■

To be continued.

vide amateur radio with growth and to offer a reasonable alternative to CB manufacturers to opening a Citizens Band in the amateur 220 MHz band. Now that history has eliminated the need for a Communicator license, will we be able to stop the FCC?

HAM GEAR FOR HAMS

Somewhere around 300,000 ham transceivers have crossed over into CB hands so far . . . where will it end? The manufacturers and importers of ham rigs estimate that about 75% or more of the new rigs end up in CB hands.

Sure, the use of these transceivers by CBers in their "HF" band, those channels in the 27.5 to 28.0 MHz band, is illegal. But, like the 55 mph speed limit, the enforcement is so slight that most CBers use the band with impunity. On those frequencies, up above the hurly-burly of the "bottom 40," sidebanders sit and make skip contacts with ease. Their ham transceivers and ham power amplifiers, aided by antenna installations which would make a dedicated DXer fidgety with envy, give them a very good taste of hamming.

Most of these chaps are much like the rest of us, a fact attested to by the large number of them who are getting their ham tickets. Recent estimates from a number of ham clubs indicate that almost 90% of the people in ham classes are CBers. Most ham classes have a dropout rate of around 40%, though this depends a lot on factors such as the instructors, the code tapes used, etc. The fact remains that very few of the HFers are among the dropouts. They seem to have a much higher degree of determination to succeed. The estimate is that at least 40% of the newly-licensed hams are now coming from the HF group.

When you figure how relatively small that group is, the number of HFers getting ham licenses is most remarkable. This also may explain why we have so far had only minor trouble with HFers bootlegging in the ham bands. The redneck crowd hasn't

Try BCB DX!

-- when you're tired of twenty

Many amateurs are familiar with DXing the foreign broadcast bands in the short waves, frequently from having DXed them in the process of aiming toward their licenses. There is, however, another area of DXing which offers a far greater challenge to the DXer, although he can no more "work" this DX than he can the international broadcast stations. This is the standard AM broadcast band, from 525-1605 kilohertz.

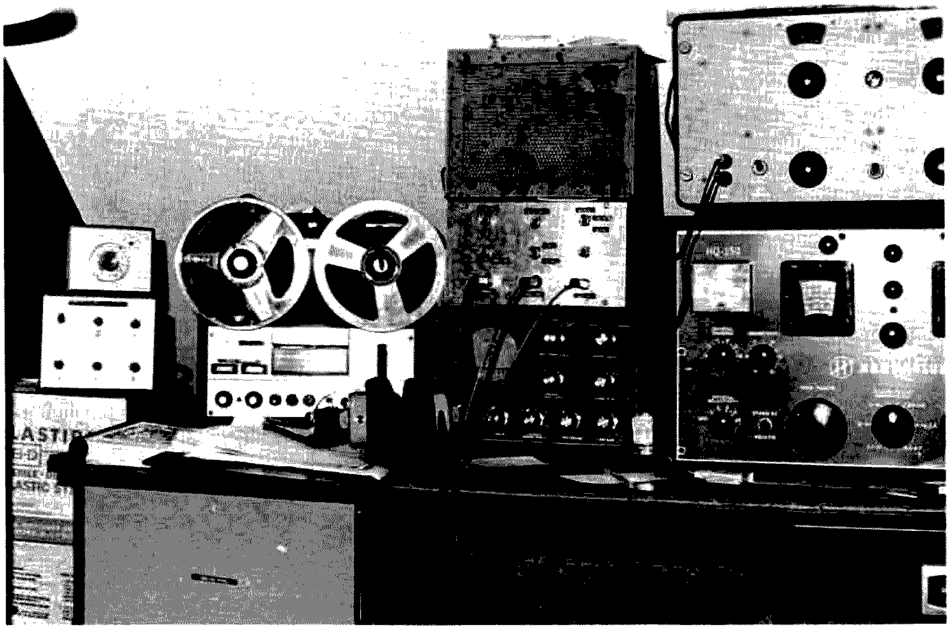
The hobby of listening on this band, like all other forms of radio listening which can be called DX, had its beginnings with amateurs. Before the advent of the commercial broadcasters on AM with which we are most familiar, amateurs pioneered here, too. Many of the oldest broadcast stations are outgrowths of amateur or other experimental operations. The first broadcast licenses were issued, indeed, for experimentation and development. Perhaps one of the most familiar of these is New York's WQXR, 1560 kHz, which was formerly W2XR.

In the old days, there were only a very few frequencies being licensed, due to the small numbers of stations and low powers involved. The present set of frequency allocations came into existence in 1934, when the old Federal Radio Commission became the familiar Federal Communications Commission. Actual commercial broadcasting, with commercial messages being broadcast as a means of revenue, began in 1924 over station WEAF (now WNBC) in New York, which broadcast spots for a Long Island realty company.

The amateur practices of sending reception reports and receiving QSL cards are also found in AM broadcast DX. Many stations will verify receptions with QSL cards or letters, although the practice is by no means as prevalent as it was in the 1920s and '30s. DX nights were common during that time, as most or all domestic stations would leave the air at local midnight on certain days, leaving the bands open for exotic international DX. Many old-time BCB DXers were able to hear and QSL stations in nearly every country which had them.

Today, however, with the over four thousand stations in the United States alone, many boasting extended schedules and higher powers, such a feat is impossible. It is, nonetheless, possible to log more than one hundred countries on the BCB. Country-counting is different from what it is on the amateur bands, and there are no DXpeditions to add to the totals, with the result that there are many fewer "BCB countries" than there are "ham countries."

But why should we DX BCB under these conditions? Perhaps the best answer is because it's there. We could well ask ourselves why we DX any band at all, and the answers would be somewhat similar. BCB offers several challenges to the DXer, including hearing stations which are not intended for long distance, international listeners, but rather for domestic ones; the challenge of beating the local QRM;



The author's shack. Left to right — clock timer with power selection panel; stereo tape recorder; speaker, audio input/output distribution panel, SB-620 spectrum analyzer; variable bandpass audio filter and HQ-150.

and the old familiar countries, state capitals, counties or what-have-you lists. Another aspect of particular importance to beginners and youngsters is the low cost and ready availability of equipment.

Equipment

All it really takes to hear BCB DX is a standard AM radio of medium to good quality, and, perhaps, a hunk of wire strung in the backyard. The best portable BCB DX equipment consists of a transistorized receiver, with a loopstick inside for an antenna, which retails for under $40.00 (the Radio Shack Long Distance TRF).

Of course, the DXer will likely wish to continuously upgrade his equipment, but a very fine setup can be assembled for less than it costs to equip a multiband ham shack with a good set of equipment. Communications receivers from the surplus market, including such makes as Hammarlund, National, Hallicrafters, Drake, or Collins, among others, are often ideal for BCB DX. Many enthusiasts consider the Hammarlund HQ-180 to be among the top receivers, while others opt for the Collins R-390A/URR. Any number of other receivers manufactured by the above companies, as well as military surplus units and current-production Radio Shack models, are also quite suitable.

Antennas are generally a home brew situation, with a four-foot air core altazimuth loop with FET rf amplifier being the ultimate of these. This is perhaps the most popular antenna in use today, although the old standby longwire and tuner is still quite prevalent. One commercially available antenna, developed by a DXer and former corporate engineer, is the Worcester Laboratories' Space Magnet series. This antenna is a ferrite-cored loop with amplifier, available in several models in the $50.00 range from Worcester Electronics Laboratories, Frankfort NY.

There are many other variations of BCB loop antennas available as construction projects, commercially available kits, or assembled units. Many DXers experiment to obtain new designs which combine high directivity, high "Q", and small space consumption to suit their individual needs.

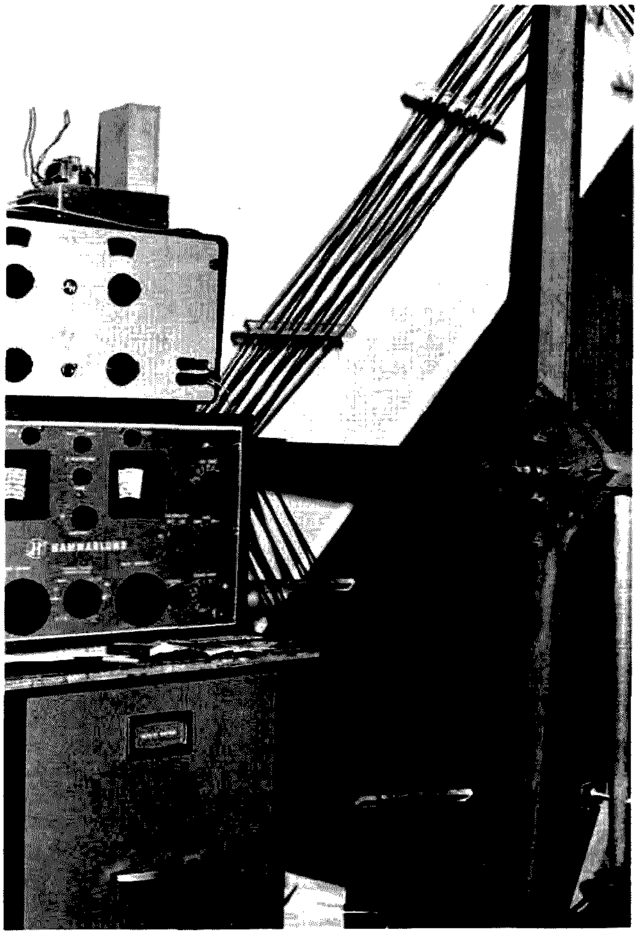
Among the most popular accessories are tape recorders, external Q-multipliers, audio filters, stereo headphones wired for mono, and oscilloscopes or spectrum analyzers. The latter are used primarily for observing signal traces and band scanning for additional signals not immediately audible, as well as for identifying interference and frequency measurement. Most of these, however, are really not necessary.

Getting Started

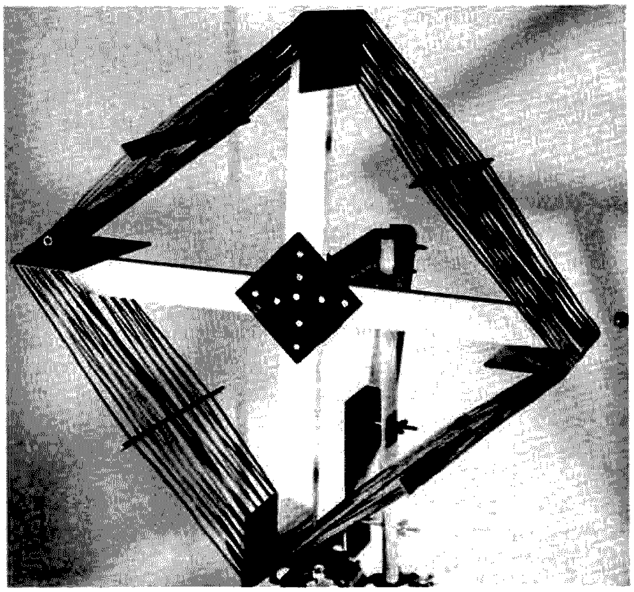
Any new hobby can be confusing to the beginner, and so it is with BCB DX. There are, however, a number of very useful publications to be had. Many of these are published by the two national BCB DX clubs – the National Radio Club, headquartered in Louisville KY, and the International Radio Club of America, in San Francisco. The two clubs were at one time one, but, as is often the case with amateur clubs, a split occurred in 1964, resulting in the two clubs. Both cover the whole continent and primarily the same segments of the hobby, although there are some differences in orientation. The NRC features more publications and a larger membership, as well as a somewhat more technically-oriented outlook.

Each of these clubs publishes a regular bulletin, which is weekly during the winter DX season, and less frequent during the summer. The NRC publishes *DX News*, which has appeared regularly since 1933. It also publishes a domestic station log, night directional antenna pattern book, receiver and antenna manuals, and a large list of article reprints. IRCA publishes a foreign log compiling all reported receptions on an annual basis, as well as a somewhat smaller list of reprints. Both publish introductory booklets. A copy of an explanatory publication and a publication list may be obtained from the NRC by writing to: NRC Membership Center, P.O. Box 118, Poquonock CT 06064. A sample bulletin may be had for 50¢, from the same address. Information on the IRCA may be obtained by writing to Richard Segalas, P.O. Box 26254, San Francisco CA 94126. Another valuable publication is the *World Radio/TV Handbook*, already known to many hams and SWLs.

Most newcomers to the BCB hobby start out with domestic DX (U.S. and Canada) and very little foreign DX. Even a casual listener will be aware that there are many stations throughout the U.S. and Canada which can be heard on even the poorest of equipment, and it naturally follows that the better the equipment and the more DX experience on the band, the more and rarer the DX will be. Much of the BCB DX hobby depends on knowing what to look for and when to look for it. For these reasons, one cannot take the publications too lightly, nor should the aspect of preplanning be



The author's shack. Variable audio filter, HQ-150, and part of 4' altazimuth FET loop. At the extreme top left is a simple fixed low pass audio filter. Not shown are mono-reel tape recorder, cassette recorder, and Nordmende Galaxy Mesa 6000 portable receiver.



A 2' altazimuth loop antenna for use with or without external rf amplifier, modified and built by the author from 4' antenna design.

ignored. Much time is wasted by beginners, who have passed the first plateau of hearing all of the regular and semi-regular stations, but have not yet learned that simply sitting and waiting for DX isn't good enough after that point.

Propagation

The optimum time for BCB DX listening is between midnight and local sunrise, when many stations are off the air, thus reducing interference and allowing DX stations through. In addition, many daytime-only stations test during this so-called "experimental period" and may, thus, be heard at far greater distances than they are normally heard during their regular broadcast schedules. Monday mornings (Sunday nights) generally yield the most silent periods from full-time stations and the most tests from daytimers, and are, therefore, the most worthwhile. Many stations conduct regularly scheduled tests during the experimental period, and lists of many of these are available from the BCB DX clubs.

Many DXers, however, find that listening during these hours conflicts with their normal lifestyle, and so such listening is confined to rare occasions. In this event, the DXer will want to capitalize on the other optimum period for BCB DX, namely the period around local sunset. At this time, propagation conditions are changing due to the sunset, and many daytime stations are leaving the air for that reason. These two factors combine to allow for more distant reception of these stations just before they do leave the air. The FCC has set out specified times for sign-offs and sign-ons of domestic stations, which correspond with their average monthly sunset and sunrise. The resulting pattern is an east to west sequence of sign-offs, thus allowing for stations to sign off leaving stations further west still on, and so on, until a full-timer becomes dominant. On some channels, a DXer may listen and hear one or two new stations signing off in every fifteen-minute sign-off period. Maps detailing the zones of monthly sign-offs (or in some cases, antenna pattern changes or power reductions for full-time stations), as well as the reciprocal times for sign-ons (and increases at sunrise), are also available through the clubs.

Propagation of domestic signals on BCB is generally accomplished by either ground wave, which follows the approximate line of sight, or by sky wave, which is reflected back to Earth in the ionosphere. Sky wave can be broken down into various levels of skip. In the daytime, the "D" and "E" layers of the ionosphere effectively prevent any significant long-distance skip on the medium waves. During the mid-winter period, receptions at distances of up to 1000 miles via ground wave are not uncommon, but, throughout the rest of the year, the average is much less.

At night, the "D" layer disappears, and the "E" layer weakens significantly, thus allowing many signals to travel on to the "F" layer, which really is composed of two layers, known as F1 and F2. During the daytime hours, these layers separate from each other to a greater distance than they are at night, but this fact is not immediately relevant to our discussion. Both "F" layers are capable, as is the "E" layer, under certain circumstances usually associated with geomagnetic disturbances known as "sporadic E," of reflecting signals back to Earth. To be technically correct, the process is really refraction, but the ultimate effect is sufficiently similar to reflection to be so called here. In general, most of the ionospheric reflection observed at BCB frequencies occurs in the F2 layer.

Normally, ground wave is reliable at night, up to a distance of approximately 125 miles. Sky wave is generally the predominant mode of propagation from about 160 miles on up. The area in between is an irregular combination of the two, with neither one dominant. It should be noted that some sky wave components will be present, but masked, at the lower distances, and that the reverse will be true at the lower range of the higher group of distances. A single hop reflection from the F2 layer can propagate a signal over a wide range of distances, up to nearly 2500 miles, depending upon the angle of radiation. A given transmitter will radiate at a multitude of angles, thus allowing it to reach the entire range of distances prescribed herein. Skyline blockage, such as mountains or large man-made structures, can prevent transmission at certain angles by blocking or absorbing the signal at either end of the path.

Long-distance (in excess of 2400 miles) propagation is primarily by multihop paths of F2 reflections. Occasionally, it may be possible for propagation by multimode paths, or other unusual modes, which are beyond the scope of this discussion. Included among these is reflection by nighttime sporadic E.

There are, however, other factors which materially affect BCB signal propagation. The most significant of these is that caused by auroral disturbances of the Earth's atmosphere. At such times, excessive absorption of sky wave signals by ionized particles in the ionosphere takes place and alters the character of reception in some areas. This alteration is geographically dependent, due to the nature of the Earth's magnetic field. It is most strongly noticed in the northeast, due to that area's proximity to the North Magnetic Pole. When this happens, absorption occurs, depending upon the severity of the disturbance, on signals arriving from the north, northeast, and northwest. In severe disturbances, or at higher latitudes, signals from the near southerly directions may also be absorbed.

This process leaves those signals which are ground wave, thus yielding signals from stations at an intermediate distance arriving

solely by ground wave, as well as those sky wave signals arriving from such a distance and/or direction as to escape the absorptive layer. Thus, signals from the south, semi-local, and local signals will predominate. It may be seen, then, that the serious DXer on BCB will frequently be as hampered by an aurora as DXers at higher frequencies are aided by it.

Planning and Recordkeeping for the DXer

Perhaps the most important part of BCB DXing involves planning the DX sessions. As noted earlier, there comes a time when simply turning on the receiver and aimlessly looking about for new stations becomes non-productive. At this point, the DXer should set about compiling realistic target station lists for each time block he plans to listen. Factors to be taken into account are interference, distance, season, and even month. The first two factors are obvious, but the latter two can use some explanation. In BCB DX, winter tends to be the primary time to listen, due to the shorter period the atmosphere is exposed to sunlight, thus allowing a lesser period of ionization to occur. Likewise, a case has been made for better propagation due to cold weather. Antenna radiation patterns are altered somewhat by a covering of snow around the antennas, and large fronts of snowy weather can often affect intermediate-range propagation by sky wave.

The month of the year is a direct factor in the sunrise and sunset times already discussed. Use of the maps of these times for domestic stations, as well as maps depicting actual sunrise and sunset times worldwide, can aid in planning the DX session by allowing you to determine when the signal path is in darkness, which predicts good propagation, or partly in sunlight, which does not. The domestic maps also allow the DXer to determine which stations lie closest to the borderline between one sign-off (or sign-on) block and another. At sunset, those stations closest to the previous block will be more likely to be heard than those closer to the following block, again due to the relative degree of darkness on the path. At sunrise, the reverse is true for sign-on DX. Even this difference of five or ten minutes in actual sunset or sunrise times among stations signing on or off simultaneously can make a significant difference.

Recordkeeping is a major part of planning, and it is also a part of "saving" your DX. Records of monthly sunrise-sunset maps for the most productive domestic frequencies may be reused year after year, as can lists of target stations. Identifying a station with marginal audio may require not only a knowledge of the rudiments, such as call letters, location, and network affiliation, but also a knowledge of programming type, special or local networks, telephone area codes, postal zip codes, sports programming, and program syndications. All of these can be used to shed light on the identity of a station for which you can pin down neither the call letters nor the location.

As noted at the outset, many DXers write for QSL cards, or "verifications of reception." This requires maintaining a log of what is heard, with an emphasis on items of local nature, advertisements, personalities, and phone numbers. This may be done via logging sheets for the long term, and by tape recordings, in order to put the data down on the logging sheets accurately. Tape recordings also allow you to play back partially-readable IDs or tentative IDs for analysis and ultimate identification. Many DXers maintain "ID tapes" which contain the station IDs recorded from DX sessions and rerecorded onto the master tapes. This creates a semi-permanent record of the individual's DX catches and provides a proof of reception as well, although not in the same way as verifications.

Table 1. Clear channel stations. All of the above stations broadcast on channels designated as "clear" channels by North American Radio Broadcasting Association agreements. All broadcast with 50,000 Watts and nondirectional antennas on a full-time basis.

What Can You Expect to Hear?

The beginning DXer might best start by trying to log as many stations on each channel as he can by day and by evening before settling down into the "DX prime time." This will weed out the regular stations from the non-regular and will give the DXer a familiarity with the band, so that he need not waste time trying to ID an unneeded station. Following that, one might try to hear all of the 50,000 Watt, class 1A "clear channel" stations, a list of which is shown in Table 1.

If foreign DX is more to the DXer's liking, or domestic DX has become boring, the beginner's goals should be toward Latin America initially, and ultimately, depending upon his geographical location, to transatlantic or transpacific DX. Here, the *World Radio/TV Handbook* is a must, in order to set up target stations, as well as to assist in identifying what is heard. Due to the fluid nature of many of these Latin American stations, as well as some differences caused by the listener's location, no list of widely heard stations will be presented. Such information, as well as information on transatlantic or transpacific DX, can best be obtained by joining one of the aforementioned BCB DX clubs.

By this time, you have either gotten interested in the concept of BCB DXing, or not. If you have, the best advice is to start out with some fairly easy targets, and to contact one or both of the two clubs mentioned. If you feel that you require still more information, again, you should contact one of the clubs, either for their descriptive material or to purchase a copy of their beginners' publications. In the meantime, good DX! ■

Build An Engine Analyzer

-- use your scope!

If you are anything like me, you hate to pay someone else to do something you can do yourself, and that's the way it is with me and my automobile. It has occurred to me that I constantly find myself involved with electronics. Yet here I am, a self-professed expert, and I have no way of taking on the complexities of the common Kettering automobile ignition system. Or do I?

Recently, my daughter, Marie, gave me a beautiful automotive timing light. It's a real peach, with an extremely bright flash, and operates from the car battery system. "Hey neat ... just what I always wanted," and, with that, I ran out to the trusty, rusty Pinto and eagerly hooked up the light to the four-banger gas burner.

The instructions say to hook the red and black wires on the light to the positive and negative terminals of the car battery and then clamp the induction pickup around the number one spark plug wire. Elementary, so far. With the engine running, and being careful to watch that those dangling wires don't drop into the spinning fan blades, I gently squeeze the trigger on the gun and watch the light spring to life. I love gadgets, and this one had all the elements of being some real fun.

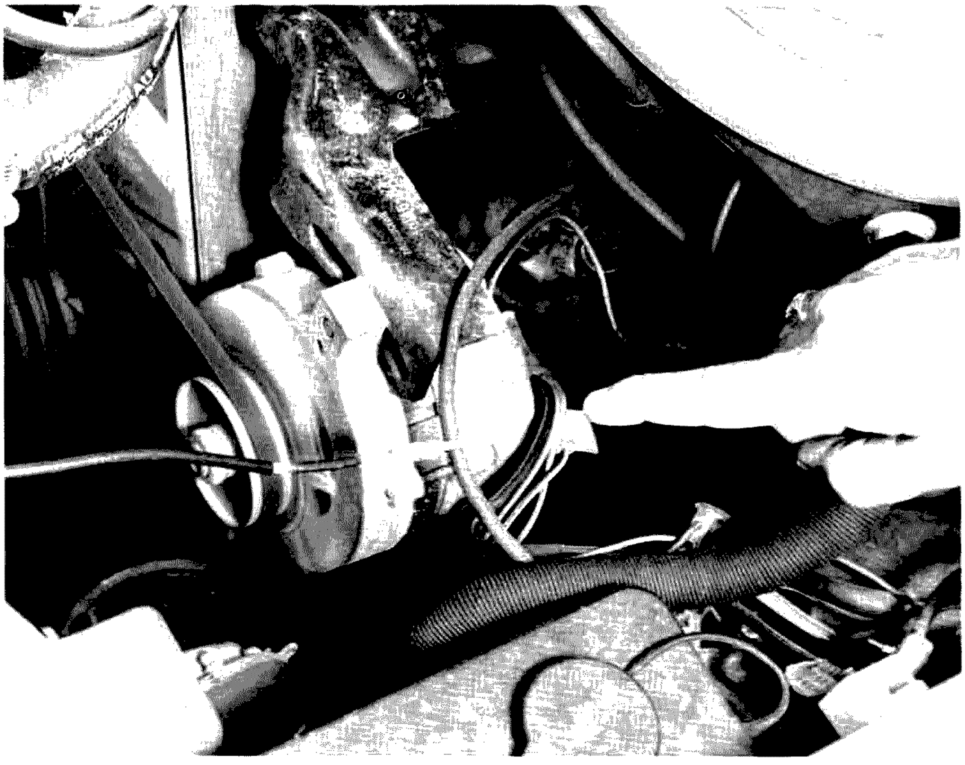

Photo A. This photo shows how the vertical input to the scope is coupled to the high tension lead from the distributor to the coil. Notice that it is only clipped to the insulation and does not make direct connection to the wire.

Now, I have fiddled around some with automotive problems and knew that the timing marks are found on the side of the front pulley. All that has to be done is to rub some chalk into those marks, so you can see them easily, and, with the timing light aimed at the spinning pulley, press the trigger and watch the strobing action, as the number one cylinder fires the timing light.

Somewhere back in my mind, I recalled that I had overlooked a few small details. Let's see . . . yes, the books did tell me that the vacuum advance line to the distributor must be pulled and plugged (I used a 6/32 bolt from the junk box), but wait, what's this? ... "Timing must be adjusted with the engine running at manufacturer's specified rpm. If necessary, use a tachometer to set idle rpm."

Well, I don't have a tachometer. The first thought that went through my mind was to run out and buy one, but that didn't settle well with me. But I needed to figure how many revolutions per minute that little Pinto engine was turning over, and with a fair degree of accuracy.

We've all seen the modern, automotive electronics shops, with their big engine analyzer scopes all nicely calibrated, but who among us is going to rush out and buy one of those? What I do have is a pretty fair B and K model 1461, 10 MHz, triggered oscilloscope, with eighteen calibrated sweep ranges. It seemed to me that that should work, somehow.

The problem was interesting and one that took my thinking through many phases. I began by thinking in terms of how the combustion engine works. It takes a fuel/air mixture into the cylinder on a downstroke, compresses it on the upstroke, where it begins burning the mixture by sparking the plug somewhere before top dead center.

The resultant explosion gives us the power downstroke. Finally, the cylinder on the last upstroke exhausts the by-products of burning. Our problem is to fire the plug at just the correct time on the first upstroke before top dead center and do this timing with the engine running at a specified number of revolutions per minute. The timing light flashing on the timing marks will show us the answer to the first problem, but that rpm problem must still be figured out. Remember, that cylinder fires only once for every *two* engine revolutions.

What we must do is get a good, *stationary* display of all cylinders firing on our scope, so we can measure the duration of all cylinder firings in time. With an externally triggered scope, this is a cinch. Take a clip lead and loosely couple it around the number one spark plug wire. I just use an ordinary clip lead with an alligator clip on one end. Clipping this around the plug wire gives me plenty of induced pulses to easily trigger the scope (see Photo A). Switching to external trigger, the scope will now make one sweep, from left to right across the tube, for every firing of that number one cylinder. Then, by coupling the vertical input of the scope to the high tension lead coming out of the center of the distributor in the same manner (see Photo B), your display will show the firings of all cylinders in exactly the sequence they actually are firing. In the case of the Pinto, it will be, first, number one cylinder, followed by three, four, and finally, number two. It's a simple matter to immediately see if all plugs are firing, and also to see the relative amplitude of the spark voltage to each cylinder. The vertical gain control, along with the vertical positioning control, can be used to bring the voltage peaks of all firings onto the scope face. Just remember, we are only looking at *induced* voltage through the insulation of the spark plug wire. We have not connected our scope directly to any bare wire, as the plug wires can carry well over 10,000 volts of ac. In some cases, it may help to put a 2200 Ohm resistor and .05 capacitor across the input of your scope, to dampen out much of the high frequency information we are not interested in. Some experimentation is called for with the exact values. Nothing is very critical in this department.

Years ago, I learned a remarkable thing that turned out to be a gem of knowledge, and, after having spoken to other people in electronics, was very surprised to learn how few understood this fact. Very simply stated: "Time in seconds is the reciprocal of frequency in Hertz, and frequency in Hertz is the reciprocal of time in seconds." Those of you who knew all along can smile, but those of you who didn't should read and reread that until you understand its exact meaning, because, with this little nugget of knowledge, many mysteries of the oscilloscope become child's play.

Remember, we want to measure engine revolutions in time – specifically, revolutions per minute. Because, as stated above, frequency in Hertz is the reciprocal of time in seconds. All we must do is measure, with the scope, the time for all cylinders to fire, take the reciprocal of this time in seconds to get frequency in Hertz, and then multiply by 120, thereby getting revolutions per minute. (Remember, that cylinder fires once every other revolution; therefore we must multiply by 120 rather than 60.)

If we look at a calibrated sweep oscilloscope, we see that sweep time is usually measured in milliseconds or microseconds per division on the graticule over the face of the tube. All we must do is count the number of divisions, generally centimeters, multiply by the indicated number of milliseconds or microseconds per division of the sweep time scale of the scope, and take the reciprocal to find frequency. At this point, a small calculator is an immense help, unless you like to do long division with a pencil.

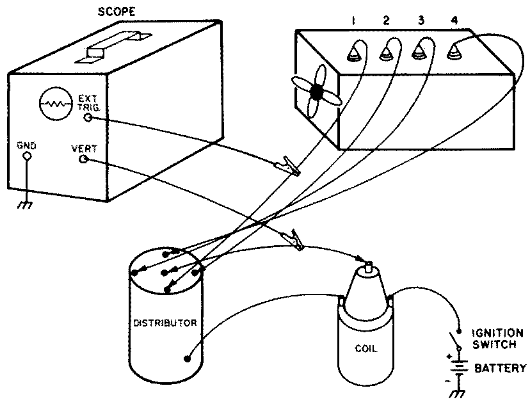

Fig. 1.

As an example, suppose we have connected our scope up as shown in Fig. 1, and we are driving a four-banger. Our sweep time is set for 5 milliseconds per centimeter. As seen in Photo C, the time between firings is 6.6 centimeters. Multiplying this by our sweep time of 5 milliseconds per centimeter, we find that time between firings is 33 milliseconds, or 132 milliseconds for four cylinders. Taking the reciprocal of 132 milliseconds and multiplying by 120 reveals our engine revolutions to be 909 revolutions per minute. For those of you who hate

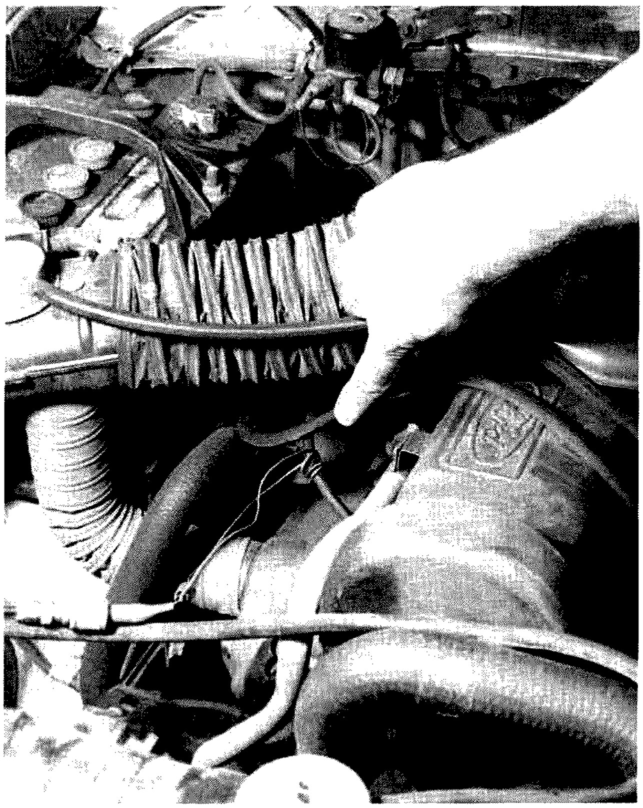

Photo B. This shows the method of obtaining the external trigger pulse from the number one cylinder. Notice that the wire is only loosely coupled around the plug wire and does not make direct connection.

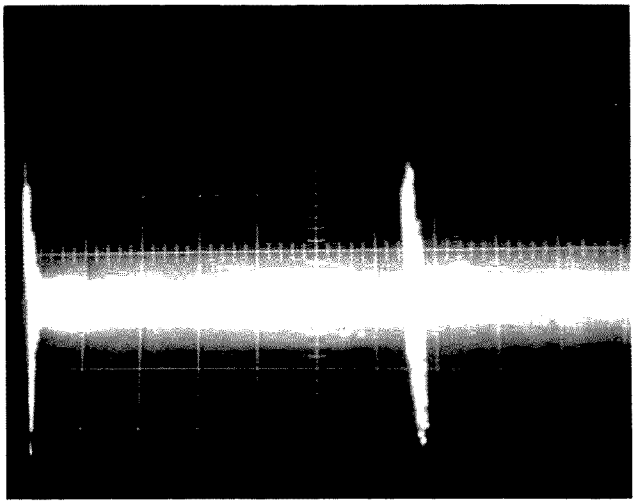

Photo C. With the sweep time of the scope set to 5 ms per centimeter, we see the time duration between two firings to be 33 milliseconds. This represents 909 rpm on a four-cylinder engine.

Engine rpm	Time for all cylinder firings in milliseconds
400	300 ms
450	266 ms
500	240 ms
550	218 ms
600	200 ms
650	185 ms
700	171 ms
750	160 ms
800	150 ms
850	141 ms
900	133 ms
950	126 ms
1000	120 ms
1050	115 ms
1100	109 ms
1150	104 ms
1200	100 ms

Fig. 2.

this kind of math, refer to Fig. 2, where I have figured out all firing times and converted them to rpm for you.

Although the scope could have been set up for a display of all four cylinder firings, I personally feel a little more accuracy is possible by using an expanded sweep and measuring the time for one cylinder firing, rather than by multiplying by the total number of cylinders. There probably isn't much difference, so it will boil down to what each individual feels most comfortable with.

To set the curb idle speed of your car, it is always best to refer to the manufacturer's specs, either in the owner's manual or in a local library, in a good automotive manual. I like *Chilton's Motor Manual* myself, and find it very complete. Generally, it's a matter of adjusting the correct screw on the carburetor. Curb idle speeds will vary, and the specs may call out different rpm for such cases as cars equipped with or without air conditioning, etc. Once the idle speed has been properly set, the timing can be adjusted with the light. This involves loosening the lock nut under the distributor and gently turning the distributor, while watching the timing marks on the front pulley in the strobing flash of the timing light. Timing will also increase or decrease the engine rpm, so you may find yourself going back and tweaking the curb idle adjust again.

A word of caution is called for here. Adjustment of engine timing and curb idle speed will affect the emissions of your car. Go slowly the first time, consult your manuals, and set your car up by the book. Don't forget to reconnect the vacuum line back onto the distributor when you are finished.

It is beyond the scope or intent of this article to go completely into electronic engine analysis and tune-up procedures. Others before me have done this with more success. All I have attempted is to introduce to you the elements of using commonly available test equipment, rather than buying specialized equipment. I have found that, with a basic single-trace, triggered scope, using calibrated sweep and a good VOM, almost any problem in the ham shack or shop can be solved with a little thinking and some understanding.

At today's prices for automotive analysis and tune-up, it won't take long before my simple equipment will pay for itself. Even if it doesn't, the satisfactions of doing it yourself, saving, and learning in the process, are the real long-term payoffs. ■

More Repeater Control Devices

-- control unit/audio interface

Over the period of the last two or three years, I have designed, built, and installed a fairly complex control system for a system of five repeaters. Three of those repeaters are local or co-located with the primary control system, while two are remote, located from 20 to 50 miles from the primary site. Since the system is now fairly well finalized, I decided to publish it. None of what is to follow was consciously copied from any other source, but, with a project of this magnitude, there are bound to be some out there who can say, "Hey, that's my circuit." To them I offer my apologies.

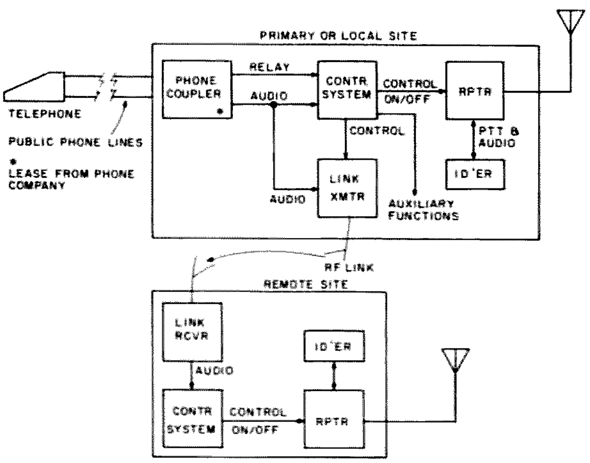

Fig. 1. Control system block diagram. Entry is via public telephone using a Ma Bell coupler. The control system then either controls the local repeater(s) directly or activates a link transmitter to relay control tones to a remote site.

The total repeater control system is shown in block diagram form in Fig. 1. All primary control functions are carried out via tone codes on public telephone lines. There is a control phone termination with a Ma Bell coupler on it. The coupler answers the line and connects the audio into the control system. It also hangs up the phone after a certain period of time. After the control phone number is dialed, a two digit control sequence is sent with touchtones™. The present equipment at the phone site has the capability of about 30 functions, but that can be changed to fit system needs.

In order to control the remote sites through the same system, one of the local control codes will turn on a 450 link transmitter and couple the telephone audio to the transmitter. Activating that code also inhibits all of the other functions at the local site while the remote is being functioned. Each of the remote sites has its own complete decoder system and its own set of control codes. The sites have a 450 receiver coupled into the control system. Under our present system, each of the remote sites has the capability of about 15 different functions, but here again, that is expandable to fit different conditions.

In addition to the control functions at each site, each has an audio interface board for the control decoder and an identifier. The identifier is a CMOS version of my original identifier circuit which appeared in the September, 1976, issue of *73*. As of this writing, the audio interface board design is not completed. I expect to complete the design in the near future. The basic theory and block diagram will be included later in this article.

The entire repeater control system is built around a two digit function code. The use of two digits was the end result of much discussion about various code lengths. It was decided that the added number of functions available or the added security afforded by more than two digits were not really worth the increase in logic complexity or cost.

The system started out entirely in TTL for economic reasons. The control at the local site was the first built and is still TTL, but the remote site equipment is CMOS and any expansion to the system will use CMOS. Only the CMOS circuitry will be discussed in this article.

Basic Control Function

The basic control function is shown in block form in Fig. 2. It consists of a tone decoder/clock generator and a function decoder. The way the system is laid out, each function decoder provides one primary function and up to four auxiliary functions. The way it works is that each

function decoder module accepts a unique primary digit (i.e., a 1) and then a second digit (i.e., 2) to complete a given function. The primary function has separate two digit ON and OFF codes having the same first digit (i.e., 1-2 ON, 1-3 OFF). The auxiliary functions all have separate ON codes, but all share a common OFF code (i.e., 1-4, 1-5, 1-6, etc., ON, 1-0 all OFF). It is possible to wire the function board to provide more than one primary function, but I didn't do it that way because it used up more of the available codes. Also, although it is feasible with this scheme, I steered clear of repeating digit coding such as 1-1.

Notice, also, that I show the digit going to the function decoder module(s). The * is a master reset which shuts off all functions at a site simultaneously. The # is used as a reset function for the initial logic states simply to eliminate possible functioning of an undesired code if doing two in sequence. For example, a sequence of 1-2 - # would turn on a function and then reset the initial stages of the decode logic. An automatic reset function is also provided which performs the same function about 10 seconds after the last tone is sent. The # and automatic reset are ORed on the decoder module, and both appear on the reset line.

Due to the many different control requirements and the low drive capability of CMOS circuits, I also provided an interface module which can provide either relay or transistor outputs or both.

Audio Interface Module

The as yet unfinished audio interface module is shown in block diagram form in Fig. 3. The module will provide the wide range agc action which is so vital to proper 567 tone decoder operation plus high group/low group tone filtering, which, while not strictly a necessity, will provide for more stable, false-free decoding. At the present time, I do have agc amplifiers on all of the decoders, but I am unhappy with the sensitivity of the circuit to the parts used. I (hopefully) will have a new design done in the near future. Also, since I'm not happy with the present circuit, I haven't designed a printed circuit board as yet.

Tone Decoder Module

The tone decoder module consists of a set of 567 tone decoders, a clock generator, and a reset generator. The basic 567 tone decoder circuit is almost right out of the *Signetics Data Book*, with only a couple of component values changed. The block diagram of the module is shown in Fig. 4, and the complete schematic in Fig. 5. NE567 tone decoders have been discussed by me (*73*, April, 1976) and many other authors, so I will forego any detailed circuit description in this article. It should be remembered, however, that the 567 output goes low with the tone present and that the NOR gates on the outputs are actually functioning as AND gates.

A look at Figs. 4 and 5 will show some circuitry not included in most decoder circuitry, but which is most necessary to allow sequential decoding. Those circuits are a clock generator and a reset generator. Gate U11 forms a circuit which will provide an output whenever any column tone is present. The output of this circuit is used to drive the clock and reset pulse generators.

As you look at the clock and reset circuits, you may well ask, "Why the gates instead of monostable multivibrators (74121, 74123, 14528)?" Well, the TTL version I mentioned earlier uses 74121s, and they gave me fits with false and double triggering. The CMOS version wasn't readily available to me.

While experimenting one night, I stumbled on the cir-

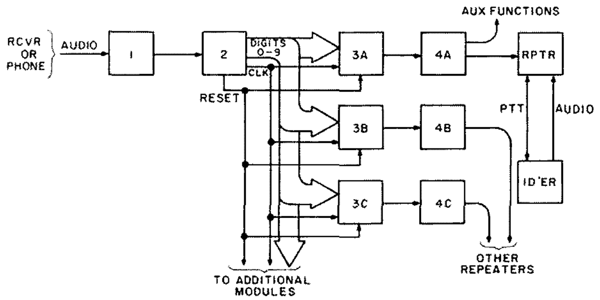

*Fig. 2. Basic control decoder block diagram. The numbers in the blocks are separate modules (1: audio interface; 2: tone decoder; 3: function decoder; 4: interface). The outputs of the tone decoder module are TTL logic levels. There is one output for each digit plus * and #. In addition, there are clock and reset pulse generator outputs. These outputs drive the function decoder module(s). The function decoder outputs, via appropriate interface module(s), control the repeater(s) and auxiliary function(s). The identifier module is a separate, independent module requiring audio and PTT to the repeater.*

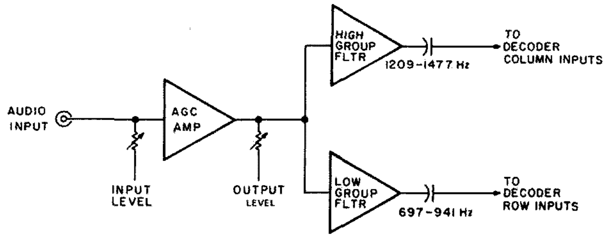

Fig. 3. Audio interface block diagram. Incoming audio passes through an agc amplifier which provides a constant output for inputs varying from about 50 mV to over 1 volt rms. The audio is then filtered into high and low tone group ranges for input to the tone decoder module.

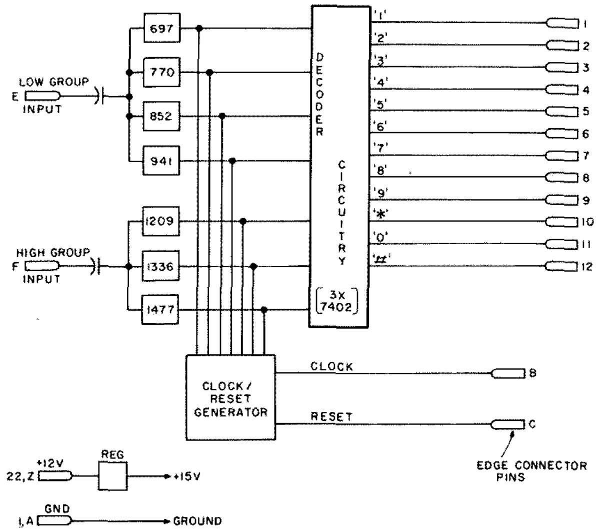

*Fig. 4. Tone decoder module block diagram. The basic decoder consists of seven 567 decoder ICs and three 7402 gate packages providing logic outputs for digits 0-9, *, and #. Additionally, the module contains clock and reset generator circuitry. This circuitry provides a clock pulse output every time a digit is decoded and a reset pulse 7-10 seconds after the last digit is decoded.*

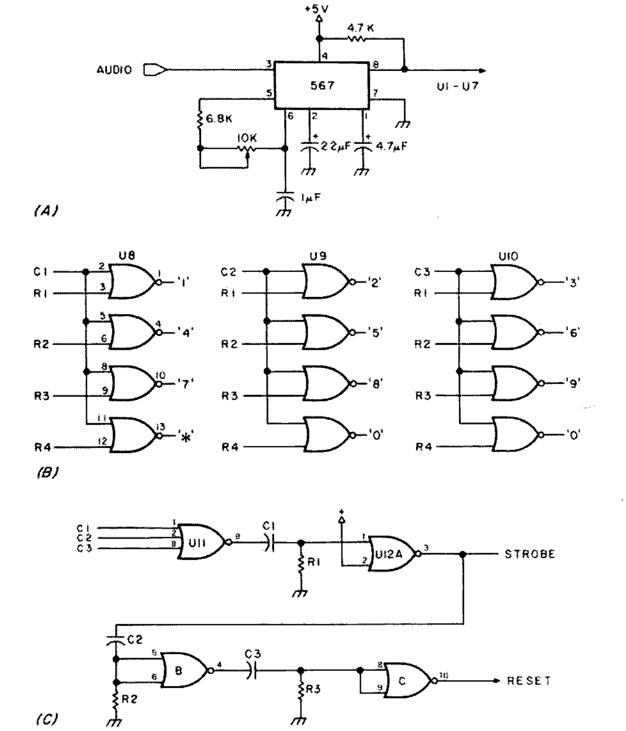

Fig. 5. Tone decoder schematic diagram. a) Individual 567 decoder; the remaining six are identical. b) Digit decoder connections. ICs U8, U9, and U10 are 7402 quad NOR gates. c) Clock and reset generator. U11 and U12 are CMOS gates 4025 and 4001, respectively.

cuit of Fig. 6, and it worked so simply and reliably that I replaced all my monostables in the CMOS designs with the gate circuit. It works in a very simple manner. When the input goes high, it charges the capacitor C to the supply voltage. Then, when the input goes back low, the capacitor has no place to discharge except through the resistor or through the input of the CMOS gate. Therefore, the output of gate U1 is a pulse whose duration is determined by the time constant RC.

As a matter of routine on this and all the other modules, I provided LED indicators on each digit output plus the reset and clock pulses. By this time, LEDs had gotten so reasonable in price that I put one on every control signal, which could be useful in determining proper circuit operation. The LEDs are driven by high gain transistor switches such as MPS6521s.

Function Decoder Module

A schematic of the function decoder module is shown in Fig. 7. Since each user would have different coding and different modules within a given system configuration, I have indicated the digits simply as D1, D2, etc.

The basic function decoder building block is the D-type flip-flop. This type flip-flop changes its Q output to agree with the D input upon application of a clock pulse. If the output was already in the same state as the D input, no change will take place in the output.

The D input of IC U1A is wired directly to the desired master digit (as explained earlier) for that function board. Then, if that digit is high (a logical 1) when a clock pulse comes along, the Q output of IC U1A will go high and remain high.

The high output of U1A then simultaneously enables all of the second digit gates (U8 and U9). The other input of gate U8C is wired to the primary function ON digit.

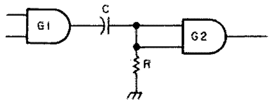

Fig. 6. Basic CMOS pulse generator. This circuit can be implemented with gates or with buffers. The one shown is a 4071 gate.

Now, assuming the master digit was sent and the ON digit is now sent, the output of U8 will go high and place a high on the D input of U1B while awaiting a clock pulse. When the clock pulse arrives, it will set the output of U1B high, thus turning on the desired function via flip-flop U2. The same clock pulse will simultaneously reset the first or master flip-flop since its D input was low during the clock pulse. About seven seconds after the last digit, a reset pulse will come along and reset U1B to a low state. This will not affect the output state.

Flip-flops U2, U3, U4, U5, and U6 are wired as set-reset flip-flops and, wired as such, provide a latching function. This function could also have been provided with cross-connected NOR or NAND gates as desired. When the high from the output of U1B is applied to the SET input of U2B, its output goes high, in turn energizing a function via the interface module. The reset input of U2B is ORed with the master reset (*) and the output of U2A which responds to the unique two digit OFF code. As a result, the function is turned off either by a two digit code or by a master reset.

The remaining auxiliary functions all activate in the same manner as the primary function and with the same first digit. The difference is in the OFF function. All of the auxiliary latch stage's resets are tied together and go to the output of U10A. They are also ORed with the master reset (*) input. With this arrangement there is one two digit code which resets all auxiliary functions at the same time, and they are also

Function	ON	OFF
Primary	6-1	6-2
Auxiliary 1	6-3	6-0
Auxiliary 2	6-4	6-0
Auxiliary 3	6-5	6-0
Auxiliary 4	6-7	6-0

Table 1. Typical function coding.

reset with the master reset. In all of the cases that I have built so far, I have used X-0 (X is the primary digit) as the auxiliary function OFF code. To make the picture a little bit more clear, refer to Table 1, which shows typical codes for a single function decoder module.

The user could alter this scheme to add more separate OFF codes, but it would be at the expense of total number of functions. For example, the F3 ON code could be wired to reset the second function instead of the common reset line.

In most cases where I have to bring a signal such as the clock onto a board and drive several devices, I have used a gate to buffer the signal before using it on the module. Also, to be on the safe side, I added buffers to each function output for more drive to the interface module. I also, as mentioned earlier, put an LED and driver on the output of each function. This proves to be an invaluable aid to both checkout and normal use. As with all the boards in this system, I provided an on-card regulator. Also, although not shown on the schematics, I put .01 uF capacitors directly across the supply pins of each device.

Interface Module

It is necessary to provide an interface between the somewhat fragile CMOS outputs and the real world of repeater controls. The circuit to be controlled might range from a Darlington transistor, requiring only microamps to operate, to a large power relay, requiring tens or hundreds of milliamps and (most probably) capable of producing a large reverse voltage spike on release. Additionally, the output might

require a switch to ground, or it might require dry (floating) relay contacts.

To take care of these diverse requirements, I have used two standard interface circuits, one transistor and one relay. The schematics are shown in Fig. 8. The transistors used are power Darlingtons requiring little drive and capable of sinking six Amps. I provided a reverse diode to clamp out any reverse spikes which might appear on the line from controlling an inductive device. In the case of the transistor outputs, they are switching to ground, and I used common phone jacks for control outputs. I mounted the jacks on a small metal panel on the front of the circuit card.

The relay output uses 12 volt PC card mount relays having contacts rated at least to 2 Amps. The relays are driven by a high gain transistor such as the MPS6521 or equivalent. I used a small barrier strip to bring out the relay contacts to the front edge of the module. If multiple relay contacts are desired from one module, they will have to be brought out to the rear edge connector.

Identifier

The identifier module is an offshoot of my original TTL design which appeared in the September, 1976, issue of *73*. The main drawback of the TTL version was the current consumption — almost one Amp.

The second problem was complexity. Most of the complexity was a result of an attempt to automatically identify about three minutes after the identifier was originally keyed, without restarting the timing circuitry.

I did some research into the memories I was using and found that I could drive the address inputs with the output of a CMOS device without destroying the device. With that in mind, I redesigned the identifier using CMOS devices for the counters and data selectors, but retaining the TTL memory and 555/556-type clock. The revised circuit with all the reidentify circuitry removed is shown in Fig. 9. The programming for the memory is shown in Table 2. The basic IDer function is the same as described in my earlier article, so I won't go into much detail here.

Briefly, operation is as follows. One half of the 556 functions as a clock which is turned on and off by the action of the start-stop flip-flop made up of U4A and U4B. The output of the clock drives counter U2, which sequences data selector U3 through each of the eight memory outputs, advances the word address by one, and then repeats the output scanning operation. This sequence is repeated until 256 bits are decoded. If different length IDs are desired, a gate could be installed to decode the outputs of the counter at the desired stopping point.

Construction

I built all of my present system on 4½ by 6½ general purpose circuit cards with 44-pin edge connectors. The cards then go in a standard rack for logic cards. This type of construction makes for easy changes and lots of versatility.

As I mentioned earlier, 1 put metal brackets on the front edge of the cards, with jacks and controls installed on the brackets.

At the time of this writing, I have started printed circuit layouts on two of the system boards, and I expect to have some of the modules available by the time the article gets into print. For information on availability and pricing write to CONTACT Electronic Research and Development, 35 W. Fairmont Dr., Tempe AZ 85281.

Interconnection and operation of a set of modules as a system is greatly aided by use of a logic card rack of some kind. I tried to make the PC cards' connections such that wiring of the logic

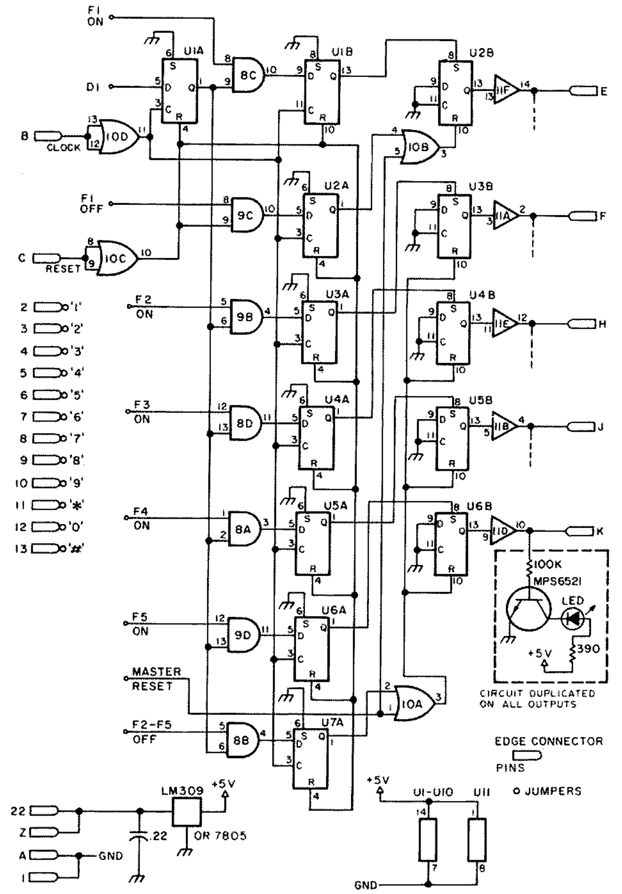

Fig. 7. Function decoder module schematic diagram. U1-U7 are 4013 CMOS dual D type flip-flops, U8 and U9 are 4071 AND gates, U10 is a 4081 OR gate, and U11 is a 4050 hex buffer. The circles on the schematic represent locations for on-board jumpers. The jumpers are for function coding.

rack wouldn't be too difficult. To make power busing easy, I made the connections on both sides of the board serve the same purpose. Terminals 1 and A are GROUND, while terminals 22 and Z are +12 V. The decoder outputs are on pins 2 through 13, and the clock and reset are on pins B and C respectively. These connections are then paralleled down a series of connectors.

Unless multiple relay contacts are desired, the only other connections on the back of the rack are a small terminal strip for power supply connection and a fuse block. I also added a 2000 uF capacitor across the supply input to the rack since the actual power source was some distance away.

Setup and Alignment

The first stage of system setup consists of deciding on the digit coding desired and then wiring the appropriate gates on each function decoder module. The PROM for the identifier must be programmed for the desired callsign. I have presented programming information in other articles, as have others, so I won't repeat it here.

Alignment is necessary on the audio and tone decoder modules. The agc amplifier input/output levels must be properly adjusted and the tone decoder frequencies must be set.

Agc alignment is easy, but requires a source of audio and an audio frequency voltmeter. First, set the audio input to the agc circuit to the maximum expected input voltage and connect the audio voltmeter to the output. Adjust the output of the agc for a convenient reading and start increasing the input level control. Increase the control until the output no longer increases. Now adjust the agc output level for the desired input to the decoder (about 150 mV rms). Now, you should be able to decrease the input from the audio source by at least one order of magnitude without the output varying.

Adjustment of the tone decoders consists of setting each 567 to its proper frequency. To be done properly, this requires a frequency counter, but it can be done with a tone pad. Power up the tone decoder module, put your counter on pin 5 of U1, and adjust the pot for a frequency of 697 Hz. In a similar manner, adjust the remaining decoders for their proper frequency. I have shown the IC numbers and frequencies in tabular form in Table 3.

Now connect the audio module and the tone decoder module together either in the logic rack or on the workbench. Here an extender board (also available from CONTACT) is a great help. Hook a touchtone generator to the audio input of the audio module and apply power to the system. Start depressing the digits on the pad. As each digit is activated, its proper LED on the tone decoder module should light, the clock LED should flash once, and, about 5-7 seconds later, the reset LED should flash.

If all of the above has progressed to a satisfactory conclusion, you are ready to plug in a function decoder module and continue testing. Once everything is connected together, sending the correct ON digits should cause the LED for that function to light, and the OFF digit should cause it to turn off.

Interface module checkout is simply a matter of seeing if the proper transistor or relay is activated when the correct function code is sent, and the proper LED on the function board is illuminated. Identifier module checkout requires either an audio amplifier or connection to your transmitter and a method of monitoring the transmitter audio. I have provided an identifier test button in the design. Every time this is pressed, the IDer will send the programmed identification and should keep the transmitter keyed through the keying transistor. The only adjustments that have to be made are the ID speed, pitch, and timeout delay.

Conclusion

A typical system configuration would consist of the following modules: audio, tone decoder, function

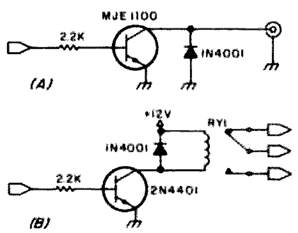

Fig. 8. Interface module schematics. a) Transistor switch. The transistor used should be a high gain one. In my case, I used MJE1100s. b) Relay output circuit. The relay driver must be a fairly high gain transistor. I normally use an MPS6521 for this type of application. The relays are PC mount with at least 2 Amp contacts. The module provides the option of using either 5 or 12 volt relays by either installing or bypassing a five volt regulator.

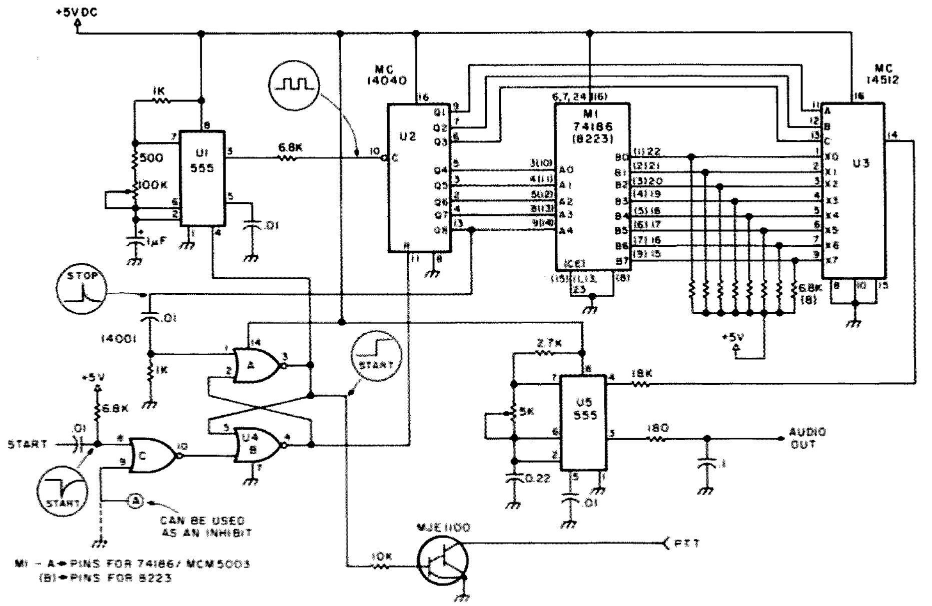

Fig. 9. CMOS identifier module schematic. The circuit is the same as my earlier article, but now in CMOS and without the automatic reidentify feature. M1 is an 8223 programmable read only memory. If more than one message or a longer one is desired, a 74186 memory could be used with appropriate wiring changes.

decoder (2), interface (2), and identifier. Addition of a COR/timer module such as laid out in my article in the January, 1977, issue of *73* would make a complete repeater control system.

I have had very good luck with this system. The only problems I have encountered were mostly my own fault. Don't use ceramic-type capacitors for the tone determining capacitors on the tone decoder module. I found out the hard way that they drift badly with temperature. I had some initial trouble with clock timing when I first went to CMOS on the function decoders, but the delay I mentioned earlier appears to have solved that problem. I got completely wiped out on a remote site once by lightning causing a surge on the power line and wiping out a lot of devices. I have since added various kinds of lightning protection on all of the sites, but I don't really know if it will be effective.

Use of this system requires a method of sending tone signals down the phone line after the line is connected at the receiving end. In some instances we have controlled our repeaters with an acoustically-coupled tone encoder, but it was not completely satisfactory. A touchtone phone is the key, but there is even a problem there. In many exchanges, Ma Bell reverses the phone line polarity when the answering connection is made, and this shuts off the tone pad in your phone so you can't send tones down the line. The answer to this problem is a little gadget the phone company will install on your phone called "polarity guard." There is no charge for the gadget itself as far as I know, but naturally it will cost you a service charge to have the thing installed.

Again, I am trying to make a complete system of module circuit boards available, but it is a slow process. If you are interested, write to CONTACT as mentioned earlier. If you decide to put one of these systems together and have any trouble, please feel free to contact me. The only thing I ask is that you include an SASE. ■

Parts List

Tone Decoder

U1-U7	NE567	7 – 2.2 uF/15 V electrolytic
U8, 9, 10	7402	7 – 4.7 uF/15 V
U11	7410	7 – .1 uF mylar
U12	4001	7 – 4.7k ¼ W
	1 - 7805	7 – 6.8k ¼ W
		7 – 10k pot

Function Decoder

U1-U7	4013	5 – MPS6521 or equiv.
U8, U9	4081	5 – LED
U10	4071	5 – 100k ¼ W
U11	4050	1 – .22 uF

Interface Boards

One of the following per controlled circuit:
MJE1100 or 2N4401
1N4001
2.2k ¼ W
12 volt relay

Identifier

U1	555 timer	1 – MJE1100	1 – 500 ¼ W
U2	4040	2 – 1k ¼ W	1 – 100k pot
U3	4512	10 – 6.8k ¼ W	1 – 5k pot
U4	4001	1 – 2.7k ¼ W	4 – .01 uF
U5	555	1 – 18k ¼ W	1 – .22 uF
M1	8223/82S23	1 – 180 ¼ W	1 – .1 uF

from page 25

amateur. It was called the FM-21, originally marketed as a six-channel radio that had twelve-channel expandability and the rather novel feature of requiring but one crystal per channel. The FM-21 has since given way to a "kissin'-country-cousin" of the two meter MK-3, the 220 MHz FM-76. Other than coverage and power output, the two radios appear to be twins. I can personally vouch for the FM-76, since one is mounted in my car and is in use daily. For better than six months, it has performed without a flaw, and, due to my life-style, I really give any mobile installation a real workout.

The FM-76 has something else going for it. As most of you are aware, the selection of 220 MHz amateur equipment is still quite limited, and if you are going to build a repeater, you have but two choices. Either you build it from scratch or you start with a good radio and build from there. Nobody has a tally, but there are many successful 220 MHz repeaters out there that got started as an FM-76. I know of at least one remote-base using an FM-76 as a 220 downlink as well. Repeater and remote-base service take a lot from any radio, and in that department, the FM-76 seems to excel.

There is more to this story, though, than radios. Very important is what does an amateur do when his radio decides to do things it's not supposed to do? Fact is, not every amateur is an rf or digital expert. When a radio decides to "go west," where do you turn? If you are lucky enough to own a Clegg radio, you simply mail it back (or drive over if you are not too far away) to Clegg Communications, and, in a few days, it's back in your hands working properly. In fact, when we drove out to Lancaster to do this story, we took with us Lou Belsky K2VMR's FM-27B. Three days later, Lou had his radio back in his car and on the air. This includes the time it spent going UPS back to Queens NY. Clegg believes that product support after sale is important and strives to supply the best in the shortest possible time. No matter where you live, if you have a way of getting your radio to Clegg, Clegg will make it play, doing so at a price that won't bankrupt you.

Clegg sells only "factory direct," and this has been the key to holding the price to where we, the amateur consumer, can afford his goodies. His current facility in Lancaster is well stocked for quick delivery and good, fast after-sale product support and service. Also available are accessories such as power supplies for base station use, antennas, and many other items we amateurs need. Soon, possibly before you read this, Ed hopes to be moving into even larger quarters that will enable him to expand his ability to meet our needs.

By listening to his peers in the amateur community, by looking ahead and being willing to "take a chance," by having something available for every VHF-interested amateur in every price range, Edward T. Clegg has become almost a legend in his own time. He's a ham who cares about amateur radio, an active amateur who keeps in tune with the needs that we have and endeavors to fill them. Moreover, as I can personally attest, he is a human being who cares a lot about his fellow man. Those of you who know him, know of what I speak; those who have never met Ed have missed something special. I sincerely hope that one of these days you have the chance I have had.

Ed Clegg pioneered VHF at a time when such was not really fashionable; he was there when it started and is still here today. There are many of us who hope that the "Man and his Radios" will be here for many years to come. Yes, I'm sold on Clegg equipment. Why not? I've owned a lot of it over the years and never once have I been dissatisfied. And I know many others who feel the same way.

How Do You Use ICs?

-- part VIII

Recently I was asked to try to unscramble a little circuit that appeared in another magazine.[1]

I didn't have all the parts needed to make the circuit, but I was able to come up with some suggestions for the correspondent, and immediately sent for the materials to build the circuit — just to make sure.

It struck me that this simple little circuit is a good demonstration of circuit function and analysis.

The circuit is an LED blinky circuit. All it does is turn two LEDs on and off alternately at a slow rate that can be seen by the eye. However, within that simple operation is the ability to show the operation of digital circuitry visually.

As a secondary benefit, you finally get to sit down and build a real live IC project, although perhaps it's not the most spectacular.

Let's take it from the beginning, the circuit analysis leading to the fault in the original circuit.

Fig. 1 is the circuit as it originally appeared.[2] You can read the circuit the way it is drawn — it is simple enough — but it will be easier if the circuit is redrawn so that the IC sections are shown individually.

This is shown in Fig. 2. The circuit uses the SN7400 IC, which has been described in a previous part of this series.

This is a four section IC. The redrawn circuit shows that two sections are not even in the circuit. They are grounded out.

That's one way to simplify a circuit. Now, for the problem. When the circuit was built as it was shown, it did not work. This was because the circuit is not correct. It is a simple defect, but let's go over the circuit closely.

The basic technical description in the original article described the circuit as a multivibrator. This is a switching oscillator. The LEDs show this operation visually. Obviously, if you build the circuit and the lights don't blink, it means the circuit doesn't work. The object in this case is to make the lights blink. That's why you built it in the first place.

However, the lights blinking is the result of circuit operation. We have eliminated two sections of the IC which are not even part of the circuit — let's cut out a bit more.

The blinky part of the IC circuit is the two remaining IC sections and the LEDs. We can see that the LEDs don't blink; what we want to know is why.

The circuit can be further divided into three main functions, any one of which could cause the malfunction.

In order to work properly, the circuit must get the correct voltage, the oscillator circuit must function, and the LED indicating circuit must function.

No work, no blinky. Now comes the easy part. You have to start troubleshooting. How do you go about it?

The voltage to an IC circuit is easy to check. In an unknown circuit, the first thing to check is the pin connections. If the Vcc and the ground pin are correctly drawn and wired, then you measure the source voltage.

If the voltage to the device terminals is within the correct range, you can eliminate it as a possible cause in a simple circuit like this. There are circuits where pulses on the voltage bus can cause mind-boggling troubles, but they won't cut off a simple circuit.

That leaves two elements. The oscillator supplies the signal that lights the LEDs, but the only function the LEDs have is as indicators. They are not part of the oscillator circuit.

In this circuit the voltage is correct, so we are left with two possible troubles. Either the LED indicator circuitry is not correct, or the oscillator is not correct.

There is not much choice, really. The first thing you have to know is if the oscillator is working. Then you can worry about the LEDs.

Now then, if the LEDs aren't going to tell you if the circuit works, what is? Let's look at the circuit again to see exactly what we are playing with.

The oscillator circuit has been redrawn in Fig. 3 without the extra section and the LEDs. We are left with the basic multivibrator.

This we have seen before. In the article dealing with the crystal oscillators, it was pointed out that they were actually not an oscillator at

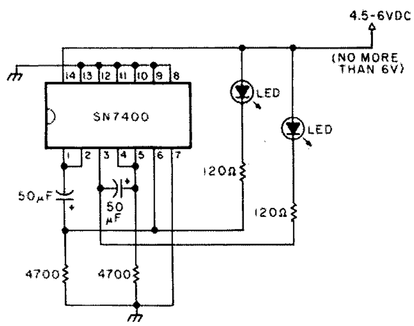

Fig. 1. Original blinky schematic (incorrect).

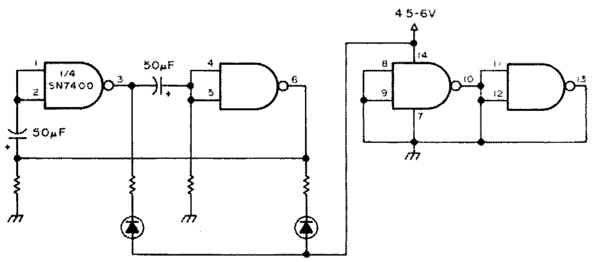

Fig. 2. Fig. 1 redrawn (still incorrect).

all, but a form of IC multivibrator circuit whose frequency of operation was determined by the crystal.

This circuit is an old friend. If you remember the basic configuration of the other circuits, the problem with this one should stand out from the page as you look at it now.

You have three basic fault choices. The IC could be defective, the parts values could be wrong or they could be defective, or the circuit could be wrong.

One of the first things that comes to mind when looking at an IC multivibrator is that normally both sections are symmetrical. Does that look symmetrical to you? That was the trouble. The circuit was incorrect. It didn't work, but how do you test it?

You test it with another indicating device. The thing to keep in mind is what it is indicating. A digital IC is a switch. It's on or it's off. In this case, it is supposed to be on and off consecutively.

As this is an oscillator, it must have a frequency. The frequency determines the test equipment to show its operation.

Here we have an awkward situation. It is supposed to flip-flop slowly enough for your eye to see the blinks. This might be a bit fast for a meter and a bit slow for a scope to really show the waveform.

When I built the test circuit (Fig. 4), I changed the values of the circuit constants. I used 2200 Ohm resistors and 0.1 uF capacitors. This raised the frequency high enough for the scope to really show the waveform.

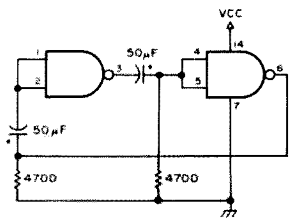

Fig. 3. Simplified circuit (Fig. 1).

Once the circuit was hooked up right, it took off the first time. Then other values were tried while it was on the scope.

It also worked with 0.01 uF caps in the circuit. This raised the frequency even higher. Now, the basic multivibrator is a symmetrical circuit. Electronically, both pulses are identical in shape and duration. It is possible to vary that to an extent.

Just to see what it looked like, one of the capacitors was made 0.1 uF and the other was made 0.01 uF. This resulted in a nonsymmetrical waveshape. One of the pulses was most definitely a different width than the other.

There is a limit to how far you can bend the circuit before it stops working, but if you have a scope, try a few different combinations to see what it looks like once you get the basic circuit working.

These values result in a switching circuit which is great for a scope but far too fast to see visually. To get back to the original idea, much larger values are used to get a lower frequency.

It is the combination of the resistor and the capacitor in each leg of the circuit which determines the frequency. Within reasonable limits, there is a wide range of combinations that can be used.

The original article suggested that no higher than 4700 Ohms be used, because it would affect the bias too much. 2200 Ohms was the highest on hand, and the 50 uF capacitors called for gave a frequency that blinked too fast. The LEDs looked like they were on continuously. The 100 uF caps slowed it down so that the blinking showed fairly clearly.

Now then, without the LEDs, how do you tell if the circuit works? First of all, it showed on the scope, but instead of seeing the familiar square wave, you got the trace being deflected at a slow rate.

What if you don't have a scope? That's simple, too. Stay with the switch action. There is a dc voltage at the output of each IC section of the multivibrator. Here the trick is making the meter show it.

In this case, you don't want a fast frequency, so start with the slow speed constants. If you have to substitute, you may come up with an inconveniently high frequency, but you still want to know if the circuit works.

If you do have a nice low frequency, you can prove circuit operation with the dc scale of your VOM or VTVM. The meter may not read correctly, but you will see the needle fluctuate up and down as the circuit switches on and off.

If you can get that, you know the circuit works. Make this test carefully. The needle may not follow the variations well, and if the frequency is too high, it will just quiver. It still tells you the circuit works, but it's really not too good for the meter – so keep an eye on it and get off fast.

If you can actually see a back and forth meter pulse rather than a fast quiver, it is a good indication that you have a nice blinking rate.

Of course, this would be the ideal situation in which to use a logic probe if you happen to have one. It will tell you immediately if the circuit is switching, and you won't have to fuss about frequency at first.

When the circuit works, you can add the indicator. In the original circuit, the LEDs went between the output and the Vcc pin. That's a bit redundant. You only need one source to light the LED. That way, it was relying on reverse biasing to turn the LED on and off.

When the test circuit was made, the LED was put between the IC stage output and ground. Thus, it was switched on when the IC section was in its high or "on" state.

Schematic symbols are nice, but if you really want to know which way is up on the LED, take one and its resistor and connect it between the Vcc pin and circuit ground. If it lights, you're OK; if not, reverse the diode. If it still doesn't light, it may be defective – try another LED.

Don't forget those resistors. As with the LED readouts, they are current-limiting resistors and just as necessary to prevent damage to the single LED. The value isn't too critical. 150 Ohms would be the smallest you would want to use; I prefer 220 or higher. If you want to be fancy, measure the actual current drawn to get the value you want.

Don't forget what you have here. The IC multivibrator is the operative part of the circuit. The LEDs merely indicate the operation visually.

The circuit constants are chosen to have a speed of operation that the eye can follow. It should be slow enough that you can easily see each LED go on and off alternately. When one looks on, the other should look off. At the least, it should show

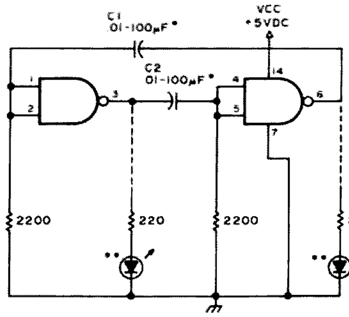

*Fig. 4. Correct multivibrator configuration test circuit. *C1, C2: both of same value. **Optional LED low speed indicators.*

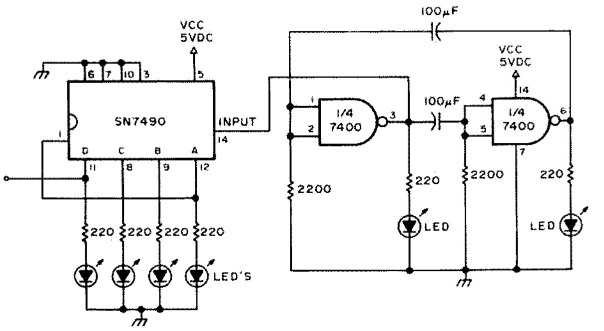

Fig. 5. Basic binary display circuit.

an alternating action, blinking back and forth.

There is another, most interesting, way of looking at what we have here. This little blinky circuit is showing us the high and low state of each section of the working part of the IC.

Since that is all that a digital IC is supposed to do – switch between two states – we can see all that it does right before our eyes.

To carry this a little further, if the speed of the switching operation is set at a speed that the eye is capable of following, much of the electronic operation of any digital circuit can be presented visually.

Even with a more complex circuit, it permits a visual understanding of the actual workings of a digital circuit that would be unobtainable easily by any other means.

This opens up a rather wide range of circuit possibilities that can be used to further your own understanding of circuit operation or as a teaching aid to demonstrate IC basics to others.

For example, the IC multivibrator circuit is quite common in ham projects. It is the basic IC oscillator. The choice of circuitry determines its function, such as crystal or audio or whatever. The basic circuit is much the same, apart from frequency.

Probably the next most important digital functions are frequency dividing/counting and circuit switching (gating).

One of the hottest ham projects going is the frequency counter. These IC functions are the main meat of the IC counter.

Fig. 5 shows a beginning application of the test demonstrator. Starting with our original blinky, which should be slow enough to see, we add an SN7490 decade counter IC. This is the basic counter circuit hooked up to show the counting action by displaying the outputs.

The second IC is hooked up to show its binary outputs. This is the whole key to the IC's ability to provide a coded output that can be translated into numbers.

This should be slow enough that the viewer can actually see the binary numbers in lights, and watch the combinations change visually with each pulse. With the explanation of the binary number system and perhaps a chart, a viewer will soon get a feel for the numbers as they change.

There you have two basic IC functions: the initial switching action and the counting action.

There are a few other points about this circuit. It may still be a bit fast when you are watching the binary numbers blink.

It is not hard to get a feel for them, but if you are using this circuit for demonstration purposes, you might consider putting in another 7490 IC stage between the multivibrator and the LED display. That will slow it down so that it can easily be followed.

You can have both 7490s set up with LEDs to give a fast/slow display. There are a lot of possible options, depending upon what you want to show.

One other thing should be mentioned. These ICs are negative edge triggered. It can be confusing at first to see that when the LED lights up at the input to the 7490, nothing happens. It doesn't pulse until the LED goes out on the negative part of the pulse.

Your eye will get used to it in a while, particularly if you understand or explain the circuit timing and what the pulses are doing.

Fig. 6 is a chart of how the LEDs will display the binary coded numbers. It takes only a short while to master it, and then it should be easy to "read" it.

Remember that it reads from right to left, each position adding to the next. There are four positions used, corresponding to 8, 4, 2, and 1. The lit positions are added together to get the total, which is the number that is counted.

Now you see what a handy little gadget the decoder/driver IC really is. It does all the work of translating the binary data to a form that can be displayed as an immediately recognizable number by the LED readout IC.

So far we can flip-flop and we can count. We can also time. Many operations in IC equipment involve the ability to switch or pulse a circuit at a specific point in the sequence.

It is a timing pulse in the counter that gates the counting circuit. This is what changes it from an event counter to a frequency counter – the ability to tie the count to a known time period.

This is usually no more than an IC gate or two. The hard part is knowing where and when to do it.

We are concerned with two specific problems: the timing of the pulse and the polarity. Both of these can be demonstrated with the addition of a few more 7400 gate sections.

You can use the unused sections of the blinky IC, but

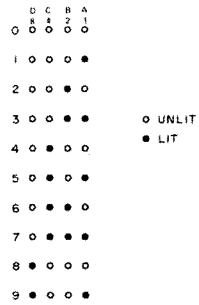

Fig. 6. Binary chart.

I found it easier to use a separate IC on another part of the IC board where it was less crowded.

Fig. 7 shows the basic takeoff circuit from one of the binary outputs. This is also the basic IC inverter circuit, so let's go into a little more detail about what's happening here.

The 7490 is being keyed by a negative pulse. This means that its input LED (at the blinky) is out of phase with the actual pulse action.

If you watch the other LED of the blinky IC circuit, it will be pulsing with the correct phase for the circuit. When it is on, it is high, which means that the other IC half is low and pulsing the 7490.

For this hookup, the takeoff was from the 1 binary output at pin 12. Now watch the relationships between the LEDs as they blink.

The blinky circuit LED to watch is the one that is *not* the input LED to the 7490. This, in effect, is the visual indication of the pulse that keys the 7490.

Notice that the blinky LED pulses twice for every blink of the LED at pin 12 of the counter IC. In effect, that part of the counter is acting as a divide-by-two circuit.

Now notice the pin 12 LED in relation to the indicator LED of the 7400 section fed by pin 12. They are out of phase. When one is on, the other is off.

Fig. 8 shows the addition of another 7400 IC section to reverse the phase of the first section. Now the LED at pin 12 and the indicator LED are in phase and blinking to-

gether.

The easiest way to demonstrate a timing pulse controlling a circuit is to use the 7490 counter's own reset circuit.

Fig. 9 shows a test circuit for this. Notice that the basic change is the connection of the 7400 switch sections to the reset pin of the 7490. Also, the switch is connected to the binary eight output and will reset the circuit to zero when the count reaches eight.

For correct counting action, at least one of the 7490's zero reset pins must be at low logic. To interrupt the counting sequence, it is only necessary to pulse the reset pin(s) to high logic.

As the pulse count changes from seven to the next pulse, it produces a high output at the binary eight pin. This same pulse appears at the reset pin of the counter IC.

When this happens, the counter automatically displays the binary zero output code: all outputs low. This happens so quickly that there is no visual binary eight output. The count goes from binary seven to binary zero, and picks up with binary one on the next count.

Thus, in effect, the eighth count is zero, which is displayed instead of an eight output code.

The counter reset can be hooked up to other binary outputs besides the eight. The four output will give you a visual count of one, two, three, and zero. The same principle holds for the two output.

While this is a simple concept to apply, there are a few pitfalls. In a counter circuit the reset action is usually keyed to the gating pulse. This is to keep them working in harmony.

You want the signal gate open for the correct time period for the count, and you want the reset action to take place when the gate is closed and be completed before the gate is open for the next count.

Otherwise, you might have the situation where the gate is open and a reset pulse appears during the count.

This means that the circuit will reset itself during the actual count, which will give you an inaccurate count. Things like this are why digital designers spend so much time making graphs and charts of circuit timing — to find these glitches on paper before they have to try and find them in their equipment.

It may seem odd to see that the output for the next counter stage is taken from the D output, which is the binary eight output.

This will take a little explaining. The problem is how to get a ten pulse out of an eight output.

The answer is to follow the actual outputs and how they affect the next stage. To do this we will pick up the count at the end of the seventh count.

Up to the end of the seventh count, there has been a low output at the binary eight output and at the input to the next stage which is fed by that output.

As the next negative pulse hits the first counter stage, it causes a high output at the binary eight output and at the input to the next counter stage.

This does nothing to the next stage. The counter is negative edge triggered. A high output means nothing to it yet, except to prepare it for the next negative pulse.

At the end of the eight count, the binary eight output of the first IC remains high. This is important. It stays on the whole cycle.

The ninth count adds a high output at the binary one output, and does nothing to the eight output, which is still on. All this while, there has been no change to the next IC stage.

At the tenth count, all of the binary outputs go to low (which is the binary for zero). At that point, the low logic is also fed to the next stage.

Since this stage is looking

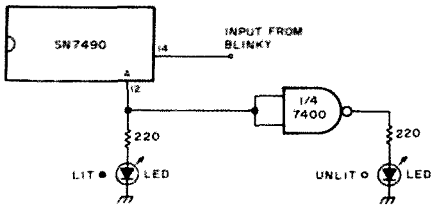

Fig. 7. Inverted output indicator or switch section.

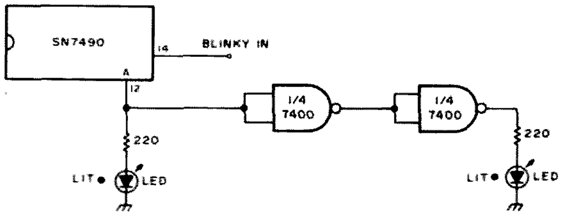

Fig. 8. Non-inverted output indicator or switch.

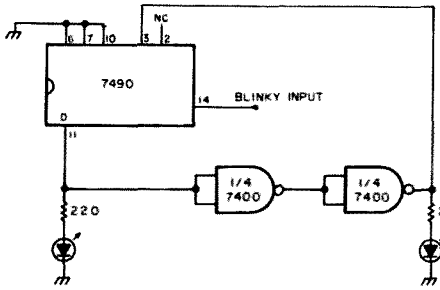

Fig. 9. Non-inverting switch used to reset counter (at 8 count).

for a low logic input, it registers its first count of one. Thus, even though the output of the binary eight output only registers as eight, its logic results in the needed pulse at ten for the next stage to begin counting.

There is one obvious thing about this test circuit. Since the output pulse and the pulse from the IC train which resets the counter are the same phase, the logical question would be, "Why not use the pulse from the IC itself to reset, instead of adding another circuit?"

In this circuit, you can do just that. It works just as well. The circuit counts to seven, and on the eighth pulse resets to zero and begins the counting sequence again.

However, that would not show the IC used as a switch. In many circuits you will not have the option of letting the IC switch itself. You will need separate switching action that can be controlled as you need it.

It is probable that there are many other circuits that can be coupled to LED indicators for a visual demonstration of circuit operation, but you will have to be careful.

Not all IC outputs will drive an LED, and you may cause damage trying. I shot a handful of 7490s trying to couple to the divide-by-two, -five and -ten hookup. They still work as counters, but not as dividers.

You may also have problems because of the phase of the TTL logic (most of which appears to be negative edge triggered). That means that the LEDs may not be on when you want them.

Still, for a few dollars worth of parts, there are a variety of IC operations which can help you become familiar with digital IC operation through hands-on practice. ■

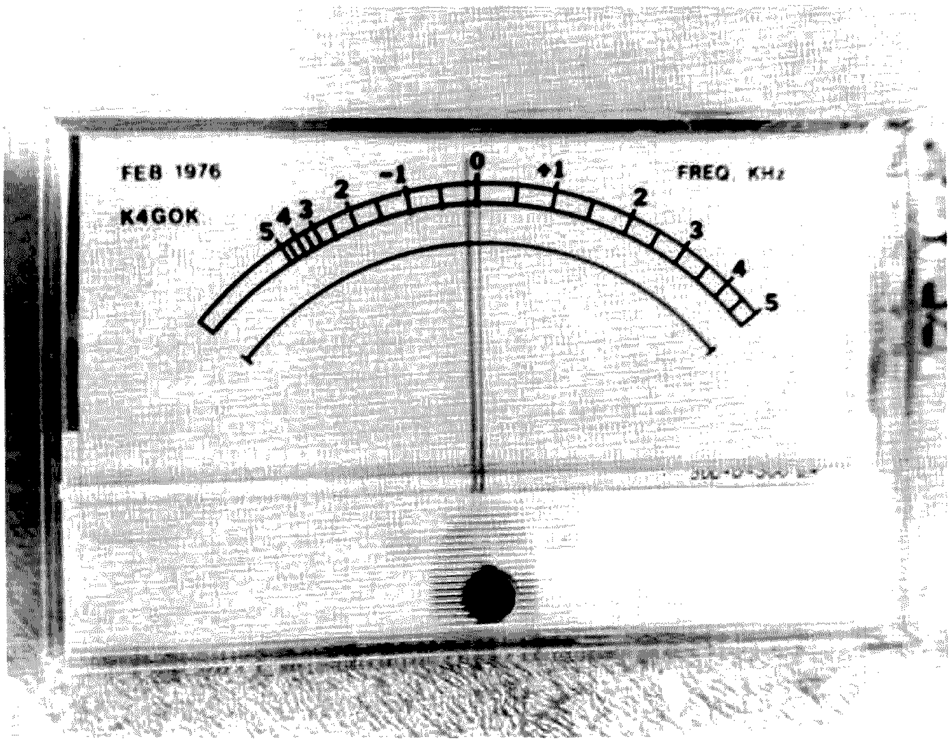
Finally! A Practical Discriminator!

-- metering system, that is

Marion D. Kitchens K4GOK
7100 Mercury Ave.
Haymarket VA 22069



The prototype discriminator meter, the particular one used and described in the design process.

The do-it-yourself amateur can easily improve the FM station by the addition of a simple discriminator meter. The meter can be calibrated to read directly the difference between the transmitting frequency being received and the frequency to which the receiver is tuned. Receiver crystals can be trimmed precisely to local repeater frequencies. You can help other amateurs align their transmit crystals to the same frequency, which is a big help in getting everybody on the correct input frequency to your local repeater.

This article describes the design process used and the results obtained in building a discriminator meter for an Ultracom 25 2 meter transceiver. Although the particular design presented here was based on components in my possession, the procedure is described so that custom designs can be made with the particular equipment and components the builder may

already have. Assumptions are made in the analyses to keep the mathematics to the simplicity of Ohm's Law.

Discriminator Characteristics

First, the characteristics of the discriminator must be determined. The discriminator alignment procedure for the builder's receiver will be of assistance in locating the discriminator signal input point and the discriminator output point. An accurate means of determining the discriminator input frequency must be available. A signal generator and digital counter are preferred. Fig. 1 shows the arrangement used to determine the discriminator output voltage as a function of the input frequency. Fig. 2 shows the results obtained for the Ultracom 25. The discriminator provides approximately .2 volts change for each kHz frequency change, at frequencies near its 455 kHz center frequency. This characteristic is reasonably linear up to about 460 kHz, but is highly nonlinear as the frequency decreases below about 450 kHz. (The audio characteristics of the discriminator are quite different than the dc characteristics of interest here – don't worry about nonlinearity in the audio responses.) A reasonable frequency range for most needs is about ±5 kHz. Examination of Fig. 2 shows that a voltmeter covering +1.0 volts to -0.8 volts could be used, if properly calibrated, to read directly frequencies ±5 kHz from the discriminator center frequency.

A surplus 1 mA 4-inch meter was available. Upon careful disassembly, it was found that this meter could be converted to a 500-0-500 uA meter by repositioning the friction-mounted return springs. The meter internal resistance was about 200 Ohms, much too low to be connected directly to the high impedance discriminator output. If a very sensitive meter, say 50-0-50 uA or better, is available, it may be practical to simply add the proper series resistor and connect it directly without unduly loading the discriminator output. It is worth a try.

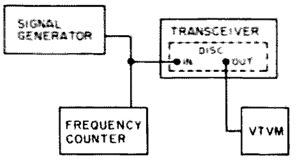


Fig. 1. Test setup for measuring discriminator characteristics.

Circuit Design

The problem for the less sensitive meter was to design a high input impedance dc circuit that would accept inputs both above and below system ground without applying bias voltage to the discriminator. The circuit must operate from a single-ended power supply (12 volts from the transceiver) for convenience and must provide both plus and minus 0.5 mA to the 200 Ohm meter. The high input impedance and zero volts dc bias can be obtained with a self-biased junction FET. The +1 volt to -0.8 volt input signal suggests an FET with a pinch-off voltage of around 2 volts. Driving the meter with plus and minus 0.5 mA suggests a bridge circuit with each bridge leg drawing about 5 mA, i.e., about 10 times the meter full scale current.

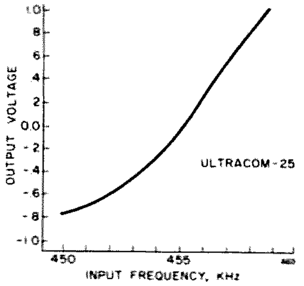

Fig. 2. Ultracom 25 discriminator dc characteristics.

The circuit then begins to take the form shown in Fig. 3. Since the meter current is not significant (< 10% of the current), the value of R4 + R5 is readily computed.

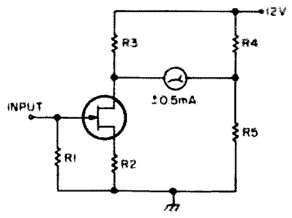

Fig. 3. Basic circuit configuration.

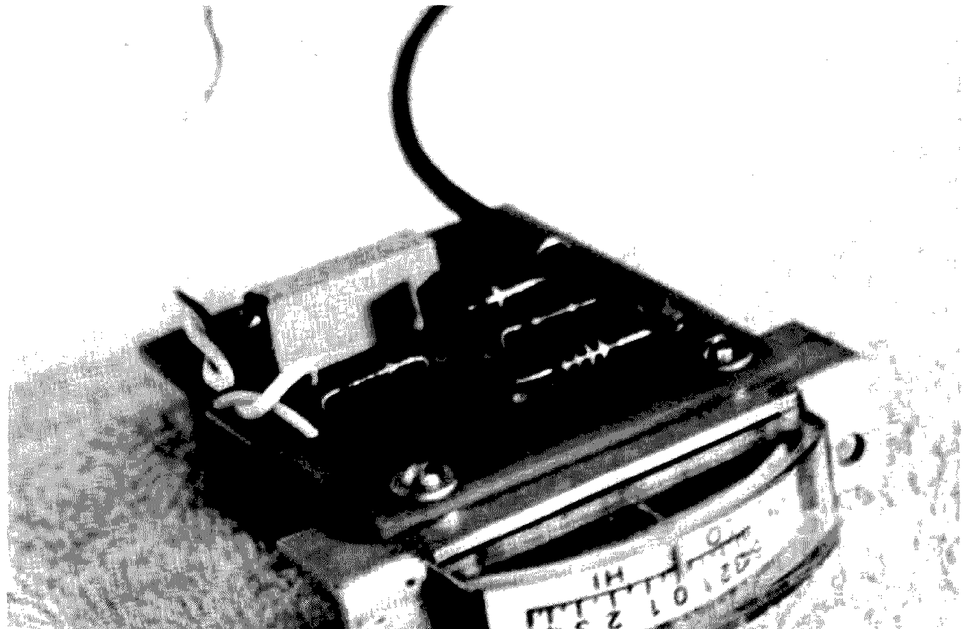
$$R4+R5 = \frac{12\ V}{.005} = 2.4k$$

Using a 2.5k pot for R4 + R5 allows for easy zeroing of the meter and accommodating variations in components of the other leg of the bridge. My circuit employed a surplus 5k ten-turn trimpot allowing easy trimming to zero.

In order to design the active leg of the bridge, it is necessary to know the characteristics of the FET to be used. The test setup shown in Fig. 4 can be used to find the FET characteristics if they are not available.



A second discriminator meter showing circuit board mounted to a small edge reading meter. This one is ready to be installed in the box housing a home brew synthesizer. The FET is a 2N3819 available from Radio Shack as RS 2035. The input pot has been replaced with a fixed resistor.

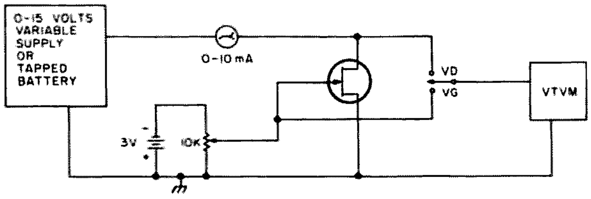


Fig. 4. Test setup for finding FET characteristics.

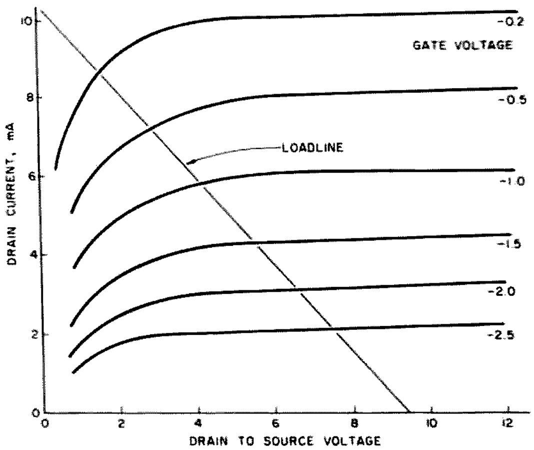

Fig. 5. FET characteristics as measured.

Several FETs from the junk box were examined and a Radio Shack N-channel FET (one of the P-channel, N-channel pair in a package) was found to have the desired characteristics. Fig. 5 shows the characteristics measured.

Once the FET characteristics are known, a bias and operating point must be determined. In general, a drain voltage of near ½ the supply voltage is desired to allow the maximum voltage gain. That is, the drain voltage can theoretically vary +½ to -½ the supply voltage if the FET drain is biased at the supply voltage midpoint. For the case in point, this ideally should occur with an FET current of about 5 mA, simultaneously with a gate self-bias of around -1.0 volt. If a gate bias of -1.5 volts is selected, a ±1.0 input swing can be tolerated without driving the FET into its pinch-off region. Examination of Fig. 5 shows that a drain voltage of 5 volts can be obtained with a -1.5 gate voltage at a current of 4.3 mA. Six and ½ volts (5 + 1.5) at the drain requires a 5.5 volt drop across R3 when the current is 4.3 mA. Note that when the bridge is balanced, no current flows through the meter and therefore all FET current flows through R3.

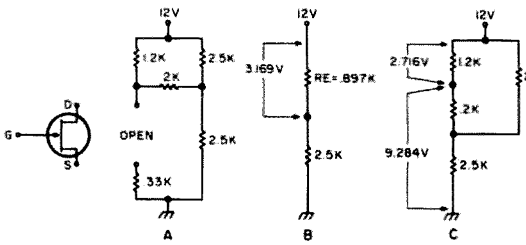

Fig. 6. Equivalent circuits when the FET is "pinched off."

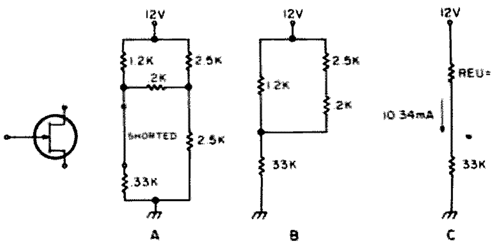

Fig. 7. Equivalent circuits when the FET is fully conducting.

$$R3 = \frac{V_{CC} - V_D}{I_D} = \frac{5.5}{.0043} = 1.28k$$

A value of 1.2k can then be used for R3.

The value of R2 can be computed from the desired gate bias (equal to the negative source voltage) and FET current.

$$R2 = \frac{1.5}{.0043} = 349$$

A 330 Ohm standard value resistor can then be used for R2.

The load line should now be drawn on the FET characteristic curves and the circuit characteristic determined. The load line can be found by considering two conditions of the FET: (1) an open circuit, and (2) a short circuit.

Consider the condition when the FET is completely "pinched off," that is, it presents an open circuit to the bridge as shown in Fig. 6(a). Equivalent circuits are shown in Figs. 6(b) and 6(c), where:

$$Re = \frac{(1.2 + .2)\,(2.5)}{(1.2 + .2) + (2.5)} = .897k$$

The voltage across Re is:

$$V_{Re} = \frac{(12)\,(.897)}{(.897) + (2.5)} = 3.196 \text{ volts}$$

and the voltage across the 1.2k resistor is:

$$V_{1.2} = \frac{(3.169)\,(1.2)}{(1.2) + (.2)} = 2.716 \text{ volts}$$

Since no current is flowing through the 330 Ohm resistor, both ends of it are at ground potential. That means that the FET source is at zero volts and its drain voltage is:

$$V_d = 12.0 - 2.716 = 9.284 \text{ volts}$$

The FET drain to source voltage is 9.284 volts when its current is zero.

When the FET is driven completely on, that is, it acts like a short circuit, the equivalent circuit is as shown in Fig. 7(a). Since the lower 2.5k resistor is large compared to the 330 Ohm resistor and the 200 Ohm meter, its effect on the circuit is small. The equivalent circuits are shown in Figs. 7(b) and 7(c). The effective resistance of the upper portion of the circuit is:

$$Reu = \frac{(1.2)\,(2.5+.2)}{1.2+2.5+0.2} = .831k$$

and the total current is then:

$$I = \frac{12}{.831 + .33} = 10.34 \text{ mA}$$

The load line can be plotted on the FET characteristic curves by locating the two points, zero volts at 10.34 mA, and 9.284 volts at zero mA. A line drawn between these two points represents the load seen by the FET.

$$R_{load} = 9.284/10.34 = .898k$$

The FET operating point, or its bias conditions with no input signal, can be found by an iterative process. First, guess a gate to source voltage, say -1.25 volts, and find from the characteristic curves the FET current and drain to source voltage at the point where the -1.25 volt gate curve intersects the load line. Fig. 5 gives values of 4.7 volts and 5.1 mA. The 5.1 mA of current through the 330 Ohm resistor produces a gate self-bias of -1.68 volts. The computed voltage and the guessed voltage should be averaged and the process repeated, using the average value as the new guess, until the computed and guessed values are equal. The operating point for the characteristic curves and load line of Fig. 5 were found to be:

-1.48 volts gate to source self-bias
5.30 volts drain to source
4.48 mA FET current

The circuit response to input signals can be determined by examining the voltages and currents along the load line. If an input signal drives the gate to source voltage from its -1.48 volt operating point to -1.00 volts, the drain to source voltage is 4.05 and the current is 5.88 mA. The input signal required is equal

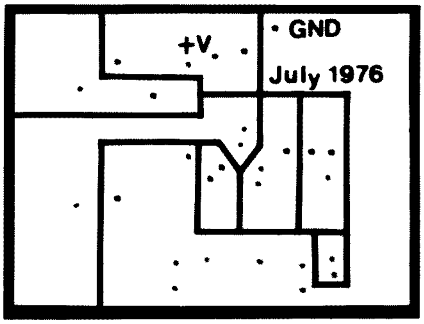

Fig. 8. Printed circuit board layout.

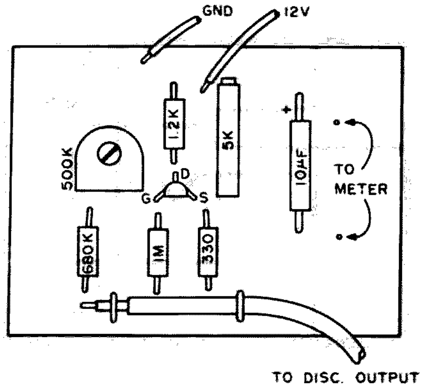

Fig. 9. Component placement.

to the -1.00 gate to source voltage plus the voltage across the 330 Ohm resistor.

$$V_{in} = -1.00 + (5.88)\ (.33) = +0.94 \text{ volts}$$

Given the voltage at the FET drain,

$$V_d = 4.05 + (5.88)\ (.33) = 5.99 \text{ volts}$$

the voltage across the 1.2k resistor and its current can be found.

$$I_{1.2} = \frac{12.0 - 5.99}{1.2} = 5.01 \text{ mA}$$

The load line indicates that 5.88 mA flow through the FET, so the additional current must flow through the meter.

$$I_m = 5.88 - 5.01 = 0.87 \text{ mA or } 870 \text{ uA}$$

The circuit response in terms of meter current for an input voltage can then be found.

$$\text{Resp} = 870/0.94 = 926 \text{ uA/volt}$$

Since the meter to be used is ±500 uA full scale, and the signal from the discriminator is about 1 volt, a voltage divider of about 2 to 1 will be required at the FET input. The circuit input impedance is determined by the 1 meg resistor between the FET gate and ground. A 680k fixed resistor in series with a 500k pot was used with the 1 meg resistor to form a divider that could be easily adjusted.

Notice the expected discriminator output voltages of +1.0 and -0.8 do not drive the circuit into regions where it cannot operate. That is, the circuit is not driven too close to zero mA current, nor is it driven to a positive gate voltage which would lower its input impedance. The circuit is also not driven near its maximum current limit. All three of these conditions should always be checked to assure proper circuit operation.

Construction

A printed circuit board layout is shown in Fig. 8. This layout fits the parts that I had, but will fit most parts by drilling holes in the correct location. The board is easy to copy with an etch resist marking pen. My assembled board was mounted by bolting directly to the meter terminals. Fig. 9 shows the parts placement.

The bridge balancing pot, R4 + R5, must be adjusted before connecting the meter to the circuit. After assembling the circuit board, apply power from the source to ultimately be used. A well-regulated power source must be used. Adjust the balancing pot for exactly zero volts across the terminals that are to be connected to the meter. Now the meter can be connected without fear of damage.

A direct reading frequency scale can be added to the meter to make it easy to use. Most military surplus meters have scales on a thin aluminum plate. This plate can usually be unscrewed and reversed, thus providing an attractive blank scale that just fits the meter. The plastic meters with permanent scales can be modified by the addition of a piece of heavy bond paper. In either case, a temporarily attached blank scale is to be calibrated. The test setup of Fig. 1 is used to accurately provide known frequencies to the discriminator. Apply power to the meter circuit and connect it to the discriminator output. Adjust the signal generator in 1 kHz steps and carefully mark the blank scale accordingly. The accuracy of the meter is determined by the precision of this calibration. Do it carefully! India ink and rub-on lettering can be used to make an attractive scale. Protect it with a light coat of clear plastic spray paint.

Using The Instrument

The meter described measures how far the discriminator input frequency is from its center frequency. The absolute accuracy with which a received signal can be measured is then dependent upon the accuracy of the receiver local oscillator ahead of the discriminator. Keep this in mind when reporting other amateurs' transmit frequencies! The discriminator meter can be used to align two transmitters to the same frequency. If a meter with a large scale is used, frequency differences of less than 100 Hz can easily be read. One hundred Hertz out of 146 MHz ain't half bad! Your receive crystals can be trimmed to frequency by listening to local repeaters and adjusting crystal trimmers until the discriminator reads zero. You will be able to measure receiver crystal warm-up frequency drift. Some of my crystals appear to drift 200 to 400 Hz. After you observe for a few months, you may suspect that some repeater output frequencies vary a few hundred Hertz from time to time. The warm-up drift of a home brew synthesizer was measured by comparing its transmit frequency with a local repeater. The transceiver receiver crystal was trimmed to the repeater frequency. A spot switch was added to the synthesizer to allow it to switch to the repeater transmit frequency while the receiver was still receiving via the crystal. An extension of this technique with several different repeaters can be a big help in getting a synthesizer on frequency without need of a frequency counter. You may find that all repeaters are not quite on their advertised frequency and that a compromise on the synthesizer frequency may have to be made to get as close as possible to all of the repeater frequencies. Readers will undoubtedly find additional uses for the discriminator meter.

Concluding Remarks

The discriminator meter was easy to design and build. It worked as expected on the first try. It was a fun project that can be duplicated in a week by just about anyone. All in all, it is a worthwhile piece of test equipment to add to the FM station. ■

A Kilowatt Alternative

-- try a gain antenna

Since the beginning of amateur radio, hams have worked on improving the efficiency of their signals. And many, not wanting to spend the time, would buy a linear amplifier, instead of putting up a decent antenna.

Although a kilowatt amplifier may boost a 200 Watt signal 6 dB, the power is often wasted by using a dipole or vertical antenna. After all, you are generally trying to communicate with one person in a distinct portion of the world at a time. Why, then, should you send your signal to all parts of the Earth? A beam or antenna array would solve this problem by directing your signal in a distinct direction. At the same time, a certain amount of gain would be realized, and QRM from many stations would be minimized.

The variety of beam antennas in use today is astounding. Each has a distinct pattern, gain, and front-to-back ratio (the difference, in dB, between a signal transmitted off the front and off the back of the antenna).

Although it is possible to buy a beam antenna, money can be saved by "rolling your own." Books are available on how to build your own beam antenna, so the remainder of this article will deal with the choosing of a beam antenna, not the construction of one.

The Yagi

The yagi is a parasitic beam antenna. This means that the reflector and director elements are not connected to the feedline.

The main element consists of a simple dipole. The reflector is slightly longer than ½ wavelength, and the directors are slightly shorter than ½ wavelength. A two-element beam, consisting of a dipole and a parasitic element, when properly adjusted, will exhibit a reasonable amount of gain. (See Fig. 1.)

All minor back lobes cannot be completely eliminated, but a gain of 5 dB is to be expected when using a two-element yagi. When another parasitic element is added, to make a three-element beam, a practical gain of 7.0 to 8.5 dB is to be expected. In general, doubling the number of parasitic elements will increase the antenna gain by 3 dB. (See Table 1.)

Yagis can be constructed out of tubing and wire. Wire yagis are identical to their pipe counterparts in operation. For best operation, a yagi should be elevated at least 30 feet off the ground.

Vertical Beams

Because a single ¼ wavelength vertical antenna does not exhibit any gain over a dipole, many hams pass by this low-angle radiator without realizing that two or more vertical antennas can be used to form specific patterns. The vertical radiates rf at a low angle, making DX much easier to work. Shown in Fig. 2 is a two-element, phased, vertical system.

Coax is used as a delay line in this system. One vertical receives rf ¼ cycle before the other one does. This way, two verticals can become an end-fire array. Note: The coaxial phasing harness lengths mentioned in Fig. 2 are electrical, not physical, lengths.

Cubical Quads

A cubical quad is an efficient, low-cost DX antenna. It is light and has a small turning radius. A quad is effective even when mounted close to the ground.

The quad consists of a simple loop, with reflector and director loops. Although the quad may be more difficult to build and erect than a yagi, the gain compares very favorably to that of a yagi. More details can be found in William Orr's book, *All About Cubical Quad Antennas*.

Long Wires

Single long wires, vee beams, and rhombics are very effective DX antennas. They have a high amount of gain. I am not going to go into the details of any of these antennas, however, for most hams would not have the amount of land necessary for them. For those who are interested in long wire antennas, the *ARRL Antenna Book* should prove quite useful. ■

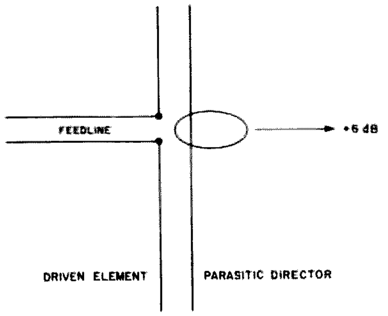

Fig. 1.

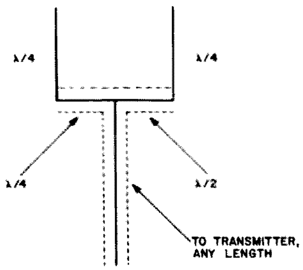

Fig. 2.

4 elements (3 parasitics)	9 dB*
7 elements	12 dB*
19 elements	15 dB*
56 elements	18 dB*
933 elements	27 dB*

*Table 1. *Gain will be slightly less, in actual practice, by about 1 dB.*

All About Transceivers

-- Novices, take note!

Many radio amateurs are searching for their dream transceiver or their dream station and are finding the search and selection difficult. Selection, unfortunately, is most frequently based upon cost rather than performance characteristics.

Dream stations have been described many times over the years – the best in spark gap and audions, a Collins station, all solid state, all mode (AM, FM, SSB, FSK, ATV, SSTV, EME, etc.) stations, and computer controlled or "the lazy man's station." Every amateur has visions of his dream station, and as the years progress, these visions change.

What you may set as criteria for that dream rig (size, power, all mode, sensitivity, selectivity, stability, frequency coverage, etc.) are not the same as some I must also consider: Does its appearance please the XYL? Does it fit the shack decor? Does it have pretty lights? "You have to sell your other stuff before you can buy anything new!", etc.

Since my XYL (WB5TNI) finally got her license after 27 years, I am at the stage of converting my tube-type, patchwork station into some type of unified, solid state station which we can both use. First we must consider the heart of the station, a separate transmitter and receiver or a transceiver. We chose to go for a transceiver to which we hope to add a remote vfo to give split frequency capability.

Most rigs have much in common as far as basic characteristics are concerned – they cost more than I can afford, they do not cover all the frequencies I wish to operate (how am I going to cover MARS frequencies?), they do not function in all modes I wish to use, they have insufficient power at a critical moment in the QSO, and they are not quite sensitive enough to pull that station out of the DX muck. I am sure that you can think of other basic characteristics.

A dream transceiver, or dream station, must fulfill your needs. How do you like to operate in amateur radio – CW, SSB, RTTY, SSTV, ATV, VHF, EME, satellites, rag chew, Technician, Novice, General, Advanced, or Extra? Many factors must be considered when we get down to actual hardware.

A station for the professional Novice would seem fairly simple to dream up as the maximum parameters have been established by the FCC – 250 Watts, vfo, CW only, and limited frequencies. One still has to choose between solid state versus tubes, kits versus factory-built equipment, and new versus old (used). However, most Novices look forward to advancing to higher class licenses. These Novices must consider most of the same criteria as the General or higher class licensee if they wish to grow into their rig. Many of the characteristics looked for by the Novice would also be good for more advanced licenses.

The vfo must be stable, and there should be provision for offset tuning. As a Novice, one needs only CW, but the transmitter should key cleanly (without chirps) and have a fast break-in mechanism. Almost all current new equipment will meet these criteria. Equipment designed for a specific small number of frequencies can be better designed than that for a larger range. A CW filter with 400 cycles or less passband is a must for CW enthusiasts. Selectivity, the ability to separate one signal from another, should also be good. Sensitivity, to dig signals from the muck, ideally should be 0.5 uV or less on all bands. Although most transceivers have a very narrow output impedance (50-70) Ohms), the ability to tune the output over a wider range would be helpful.

The Technician's requirements on the high frequency bands are the same as the Novice's. However, he has a range of choices in the VHF bands. We will not discuss VHF in this article.

We really come to a wide range of choice with the General, Advanced, or Extra class licensee. A good method of making a choice among the many currently available transceivers is to listen to the discussions of amateurs on the air. Amateurs are fairly free with their comments concerning the good and bad characteristics of the various rigs. Another method is to listen to the quality of the rigs you hear on the air.

In our area, the popular transceivers seem to be the Heath SB series, Kenwood TS-520, Yaesu, and Drake. The Swan transceivers have

never been popular here. We are also noting a decrease in popularity of the Drake TR-4C and the Yaesu FT-101. The Kenwood and Atlas transceivers seem to be increasing in popularity. Five years ago, the Drake, Heath, and Yaesu were the most popular units. I personally have a Swan-350 which is one continuous headache, and a borrowed Drake TR-4. The TR-4, in the experience of hams in this area, is a better rig than the TR-4C. In our area, there are probably more Kenwood TS-520s (with Heath being second) than any other rig. (In our charts, the Tempo "one" is added for consideration as some amateurs still prefer tube-type units. Collins is not considered, due particularly to cost, the fact that other transceivers can outperform the KWM-2, and because the KWM-2 has not been modernized for many years.)

If I were to buy a new rig today, I would have great difficulty deciding just what I would choose. Even after the research I have done for this article, I still find choice confusing. I like some features on one unit, and others I don't like. So it goes with all available units. My dream transceiver has yet to be designed and built. However, each of us has our own requirements, and we must compromise with what is available.

What would I like for my dream transceiver? Cost should be below $500 (but that is impossible in the current market); built-in ac and dc power supply; variable power — 100 to 150 Watts PEP output, with capabilities of going to 300 Watts PEP output when the going gets rough; full coverage of all HF amateur bands, plus enough extra on the ends to cover MARS frequencies; capabilities built-in for CW, SSB, FSK and AFSK, and adaptable to SSTV; digital dial backed by an accurate frequency counter; WWV monitoring capability on 10 and 15 MHz; VOX and push-to-talk; all solid state; separate vfo to use split frequencies for DX; sensitivity on all bands of 0.25 uV, or less, for 10 dB S+N/N; carrier suppression of 60 dB or better, unwanted sideband suppression of 60 dB or better, and spurious and harmonics down by at least 60 dB; and selectivity of 2.1 kHz at -6 dB on SSB, and not much greater than that at -100 dB. On CW I would like a filter or selectivity of about 150 Hz. And, of course, I would like a noise blanker and a sidetone monitor.

Fig. 2. Transceiver basic characteristics. + = present in transceiver, - = not present, OPT = optional accessory.

The Tempo 2020 and Hy-Gain 3750 are still rather unknown quantities, although the specs look good. We are beginning to see more and more Japanese-built rigs that seem to be the same basic unit with only the name plate, front panel, and a few options difference.

Although there are many ways to broadly divide transceivers into groups, the following are usually the first considered:

Cost: Below $500, $500-1000, $1000-2000, and over $2000. New versus used equipment.

Construction: Kits versus factory-assembled. Solid state, tubes, hybrid.

Modes: CW only; CW/SSB; CW/AM/SSB; CW/SSB/AM/FSK.

Frequency: Single band versus allband, or multiband; vfo, crystal, synthesizer.

New equipment and new models of present equipment are coming out at all times, so what is said in this article may be superseded shortly. Heathkit is featuring the SB-104 which has superseded other units in the SB series. Although the Heathkit HW-101 is still advertised, it appears the HW-104 is destined to replace the HW-101. Kenwood brought out the TS-520, and shortly thereafter the TS-820 appeared on the market. Yaesu is also bringing out new models — first the FT-101, then the FT-101B, the FT-101E and EE, and now the FT-301D. With every new model the price seems to go up. There are now very few, if any, transceivers selling new for under $500 if one considers the total cost of putting the transceiver on the air.

The question of new versus used is faced by both the newcomer and the established amateur. New units have a much better warranty than used units, but if repairs are needed, how long would it take to get the unit repaired under warranty? Where does one have to send the transceiver for warranty repairs? There are different types of warranties — factory and dealer. A few dealers also offer warranties in addition to the factory warranty.

*Fig. 1. Cost comparison. X = Built into the transceiver, N/A = Not available, ? = not known. Available options are listed with cost. *Auxiliary vfo Model 206 (digital dial) provides complete coverage of 3-5, 6-8, 8-10, 14-16, 20-22, and 28-30 MHz. (206 also functions independently as a 100 Hz-40 MHz frequency counter. Price $299.) **Built into ac power supply console. ***Available as an option at one time, no longer listed.*

Questions to ask are where the repair work will be done — factory or local dealer — and how long it will take for repairs.

When buying used equipment, you may be buying someone else's troubles. If you buy either new or used equipment, you should buy from a reputable firm or person. In the charts we list new and used prices as published in amateur journals by reputable firms. Used prices from individuals can vary greatly, as can equipment condition. Locally, the maximum used price is at least 15-20% less than east coast or west coast prices. Used prices from individuals are usually less than used prices from retail stores.

If you do not know which are reliable companies, then ask your friends who may have had dealings with the firms or listen to the comments made on the air by other amateurs.

Buying used equipment from individuals can be very hazardous, particularly if you do not know how to judge used equipment. It is best to take a friend with you who can judge used equipment. If possible, take a friend who owns a unit like the unit you are considering or has had some experience operating such a unit.

Several points should be kept in mind when buying used equipment. First comes visual inspection, externally and internally. Is the unit clean or beat-up? Have modifications been made on the unit? Is there evidence of rewiring or soldering not of factory manufacture or not equal to factory quality soldering? Are there any additional holes in the cabinet or chassis that were not there when the unit came from the factory? Also determine if repair parts are still available. Some of the older units are sold as is because repair parts are difficult to obtain. Other units are difficult to repair because the manufacturer has gone out of business, or has gone out of the amateur radio business.

Second, you should check the receive characteristics. Attach the transceiver to an antenna and check the receive characteristics on all bands. Is it noisy? Does it separate the signals well? Does the S-meter work? Compare sensitivity, or ability to pick up weak signals, with a unit you know works properly. Is there distortion or a broken cone in the speaker? Do you get ringing on SSB or when the CW filter is used? Does it cover the frequencies you wish to work? Does the crystal calibrator work?

If the receive section seems to work well, then check the transmit section. If possible, make on-the-air contacts, and get reports. Terminate the output of the transmitter through a wattmeter into a dummy load to measure output power. Can you load it to full rated power on each band? Are the final tubes soft? Does the transmitter cover the frequencies which you would like to work? Do you get maximum output at the point where you get the maximum dip on the plate-current meter? If not, you may find the transmitter is improperly neutralized.

Fig. 1 is a cost comparison chart. The most important figure is the *total*, which is what it would cost to put a new unit on the air (exclusive of the antenna system) at the level to include options that may be standard on other units. For example, some units have noise blankers as standard equipment, whereas this may be optional with others. The cost of such options is included in the total. We also include both ac and dc power supply cost in the total. Under microphone, we list the cost of factory recommendations, but it is realized that cheaper microphones are available. Some units have built-in speakers, but an external speaker is usually to be preferred. Three of the listed transceivers have digital readouts based upon frequency counters, and one has a hybrid readout combining a digital readout for megahertz and kilohertz and a dial for hundreds of cycles. Most of the units have frequency readouts resettable within ±1-2 kHz and a drift of less than 100 Hz after warm-up.

The FCC requires that the amateur licensee have some method of measuring transmitter frequency independent of the frequency-determining device of the transmitter itself. Most amateurs meet this requirement by using a calibrated receiver with a 100 kHz and/or 25 kHz crystal calibrator which has been zero beat with one of the primary frequencies of WWV. Some transceivers have WWV receive capability, others do not. A few can receive WWV on both 10 MHz and 15 MHz. The capability to receive WWV is a desirable feature on a transceiver. In the chart, *crystal calibrator* refers to one with 100 kHz calibration points. A few units also have 25 kHz calibration points,

and WWV also means that the transceiver has receive capability for WWV.

All transceivers considered in the comparison did cover the full 80-40-20 and 15 meter bands and 28.5 to 29.0 MHz of the 10 meter band. In the chart, we list additional coverage by the transceivers that is in excess of these basic bands. A few units also have provision for auxiliary bands which may be determined by the user.

During years of low sunspot activity, there is considerable activity on the 160 meter band, even though there are frequency and power restrictions in certain geographic areas for use of this band. I personally would not pay extra for the 160 meter band. However, it is important to me that a transceiver be able to cover at least to 29.5 MHz for OSCAR activity and that it cover sufficiently beyond the band edges for MARS frequencies. It is important to consider the total coverage of the transceiver — if you don't want the extra coverage now, you may want it in the future.

Some transceivers have selectable sideband on all frequencies, others have only lower sideband on 80 and 40 meters and only upper sideband on 20-15-10 meters. In our chart, an X in the LSB/USB column means the unit has selectable sideband. The lack of selectable sideband is not a serious detraction, as most amateurs use only the lower sideband on 80 and 40 and only upper sideband on 20, 15, and 10 meters.

Final amplifier input power is limited to a maximum of 250 Watts for Novices and Technicians, and other classes of licensees have a maximum input of 1,000 Watts for CW and AM, and 2,000 Watts PEP for sideband. FCC regulations state that an amateur should use the minimum amount of power necessary to maintain communications. For each 3 dB increase, one must double the power. Assuming 100 Watts output as the baseline, one must go to 200 Watts to bring about a noticeable difference in reception over 100 Watts, to 400 Watts for 3 dB increase over 200 Watts, and 800 Watts output from 400 for another 3 dB increase. Generally, one can figure about 100 Watts output from 160-180 Watts input to the final. Most of the transceivers reviewed had an input of about 200 Watts and generally can produce satisfactory communications.

Many amateur radio magazines — *Ham Radio, QST, 73* — carry articles evaluating in depth new equipment as it is marketed. These are usually good sources of unbiased technical evaluations, and usually indicate how the particular unit under test compared with the manufacturer's published specifications. We are using the manufacturer's published specifications in our comparison charts.

Sensitivity is the ability of a receiver to pull in weak signals and is rated in microvolts (uV) for 10 dB S+N/N. The 1977 *Handbook* defines sensitivity as "the signal at the input of the receiver required to give a signal plus noise output some stated ratio (generally 10 dB) above the noise output of the receiver." Sensitivity can be increased through the use of a solid state, low-noise preamplifier, as much noise is generated by thermionic emission from tubes. The amount of thermionic noise in tubes can be decreased by running them at a lower voltage — e.g., 100 V instead of 180 V — in the early stages of the receiver where the most noise is generated before the signal is adequately amplified. An all solid state receiver has a lower noise level, and usually better sensitivity than does a tube type receiver. The newer transceivers are all of the solid state variety in the receiver section. Exceptions to this statement in the comparison chart are the TR-4C and HW-101, which are predominantly tube types.

Selectivity is a measure of the ability of a receiver to separate adjacent signals. Selectivity is a measure of the width of the bandpass at a point 6 dB down (-6 dB) from the peak of the bandpass curve. For a receiver with 2.4 kHz selectivity, the bandpass is 2.4 kHz wide at -6 dB. For SSB, a selectivity of 2.1 to 2.4 kHz is good, as an SSB signal is usually no broader than 2.4 kHz. On CW, since theoretically it is a single frequency signal, the bandpass can be much narrower. Most receivers with CW filters have a 400 cycle bandpass, but some have only 150 cycle bandpass. In newer types of receivers, a crystal filter is used to provide bandpass attenuation.

The selectivity bandpass at 6 dB down must be sufficient to pass the necessary signal information (single sideband, double sidebands, or carrier plus sidebands) without undesired attenuation. An AM signal requires about twice the bandpass of an SSB signal. A CW signal, as stated previously, requires even less bandpass frequency.

If your transmitter has a sidetone oscillator, you can hear yourself as you send CW. The ability to hear yourself with a sidetone oscillator in the transmitter, or on the keyer, helps in sending better formed CW. Without being able to hear yourself send, you can have difficulty with proper spacing and formation of characters.

Other characteristics of transceivers are also important and are used as selling points in advertising. We have listed in the charts only what we consider to be the basic characteristics of importance in a good transceiver. ■

German Amateur Procedures

-- and repeater information

This article has two purposes. The first is to inform anyone who talks to a German ham on the HF bands, because he may be interested in knowing more about the other man's hobby environment. The second is to help anyone anticipating a trip or work assignment in Germany, who may well wish to do some hamming while in the country. For these reasons, this article will explain the ham license structure and hobby activities available in Germany.

Like most hams all over the world, the German ham you talk to has had to pass a series of exams. They are given by the Deutsche Bundespost. The minimum age at which one can become a ham is 16 years. There are two main divisions of licenses, the class A/B and the class C. Holders of a class A or B can operate all permissible amateur bands on all modes, with the only difference between them being the transmitter power authorized. If you've worked a German ham on the HF bands, he had either a class A or B license, because the class C license is the equivalent of the American Technician class and allows only operation above 144 MHz.

If you will refer to Table 1 for a summary of the bands and modes for each license, you will note that, unlike the American Technician class, the German class C ham may not operate CW on any band. He has not been required to pass a CW exam to get his license. This is the only difference between the class C and class A/B ham, because all hams take the same written exam on technical, regulatory, and operational subjects. The code test is at 60 characters per minute and requires a solid minute's copy each of, first, five-letter groups, then German language text, and then English language text. A maximum of three errors is permissible. If a ham has a class C license, he need only pass the code test to upgrade to a class A license.

If the exam is failed, the applicant may take it again. If the second attempt is failed, a mandatory waiting period of one year must be observed before trying again. If the third attempt is failed, a period of three years must be waited out before trying again.

License fees are paid by the month at 3 Deutsche Marks (DM) ($1.25), plus 3 DM for the issuance of a new or duplicate license. The exam costs 15 DM ($6.25) the first time and 5 DM for a repeat.

A ham must operate as a class A operator for a year's probationary period before he may upgrade his license to class B status, if his record is good. A class A station is allowed a maximum of 50 Watts final power amplifier dissipation, a class B station 150 Watts, and a class C station 50 Watts. While this system is different from the American use of power input, you can readily compare them if you refer to the normal efficiencies of SSB and FM amplifiers.

Just as in the U.S.A., you can tell something about a German ham from his callsign. Old-timers with class B licenses are assigned a DL, DK, or DJ prefix, and newer operators have a DF prefix. Class C stations are DC or DD prefixed. If the ham is not a citizen of Germany, but of another country, he receives a a DJØ class A/B prefix or a DCØFA to JƵ class C call. American military stationed in Germany receive a DA1 or DA2 prefix for a class B or a DA4 prefix for a class C license, depending on the class of their U.S. license.

To operate in Germany as an American, there are two basic systems in use. If you are a tourist, you can obtain a temporary reciprocal license commensurate with your U.S.A. license class, and you will use your U.S.A. call with a /DL. The ARRL has an information package available for your use in applying in advance for the license. Or, if you're in a hurry or already in Germany, write the German equivalent to the ARRL, the Deutscher Amateur Radio Club (DARC), at Postfach 1153, 3507 Baunatal 1, West Germany. Ask in your letter for a tourist license valid for three months, and include the following information in the format shown:

1. Family name, Christian name, nationality
2. Birthday
3. Place of birth
4. U.S.A. address
5. U.S.A. callsign
6. ARRL membership status
7. Copy of U.S.A. license
8. Dates of 3-month period desired
9. Mail address in Germany

10. Actual address in Germany
11. 15 DM international check or money order, or wire to the DARC bank account, Postscheckamt Essen 5613-430, with a note (showing your U.S.A. callsign) that it is for a tourist license.

You should expect up to six weeks processing time for your license to go through the DARC to the German authorities and back to you. If you are to be stationed in Germany with the U.S. military under the Status of Forces Act, you must go through the U.S. Army liaison office to apply for a license. Write for application forms to the Commander, 5th Signal Command, Attn: CCE-OP-T-ML, APO NY 09056. This license will be issued for a year at a time, at an annual cost of 39 DM ($16.50), by the FTZ division of the Deutsche Bundespost (DBP). It will be a class B license for all classes except Technician and Novice. Technicians receive a class C license, and Novices are not eligible for a DA call license. However, a Novice can obtain a three-month tourist license to hold him over until he can upgrade at the FCC examinations given twice a year at Ramstein Air Base, Germany.

Now that we've discussed the license and privilege structure, it's time to talk about what can be done on the air with the license. The HF bands, you will note, are smaller than in the U.S.A., but are not legally divided into modes of emission or subbands. However, "gentlemen's agreements" exist, much the same as in the U.S.A. German hams like working DX and rag chewing as much as any ham, and the usual blend of home brew and commercial equipment can be found, made by German, Japanese, and American manufacturers. Customs and taxes really elevate the prices on gear, however. Can you imagine paying $1000 for a new Drake R4B receiver or $800 for a Yaesu FT-221? "Discount" is a word not readily found in a German ham dealer's vocabulary. However, in the usual ham spirit of "keeping the rig new while forgetting to buy shoes for the family," hams manage to stay on the air. Hams here also find themselves interested in CW, SSB, SSTV, and RTTY, with, of course, the usual local and international blend of contests available to jam the weekend bands into an aspirin bottle.

Of the over 25,000 German hams, many, either because of their class C license or a genuine interest and desire for the open spaces of radio, find their interests directed towards VHF/UHF operation. It is in this area that the German hams really excel. Technical proficiency is, on the average, very high, and these bands lend themselves to home brew and antenna projects readily. As can be seen from Table 1, there are no 50 MHz or 220 MHz bands in Germany. As a result, most activity is on the 144 and 430 MHz bands, and even these bands are smaller than in the U.S.A.

There is a high degree of activity on FM using both simplex and repeaters. The main two meter and 70 cm frequencies are given in Tables 2 and 3, from which you can see that the Germans use the standard two meter 600 kHz offset, and a 7.6 MHz offset on 70 cm. There

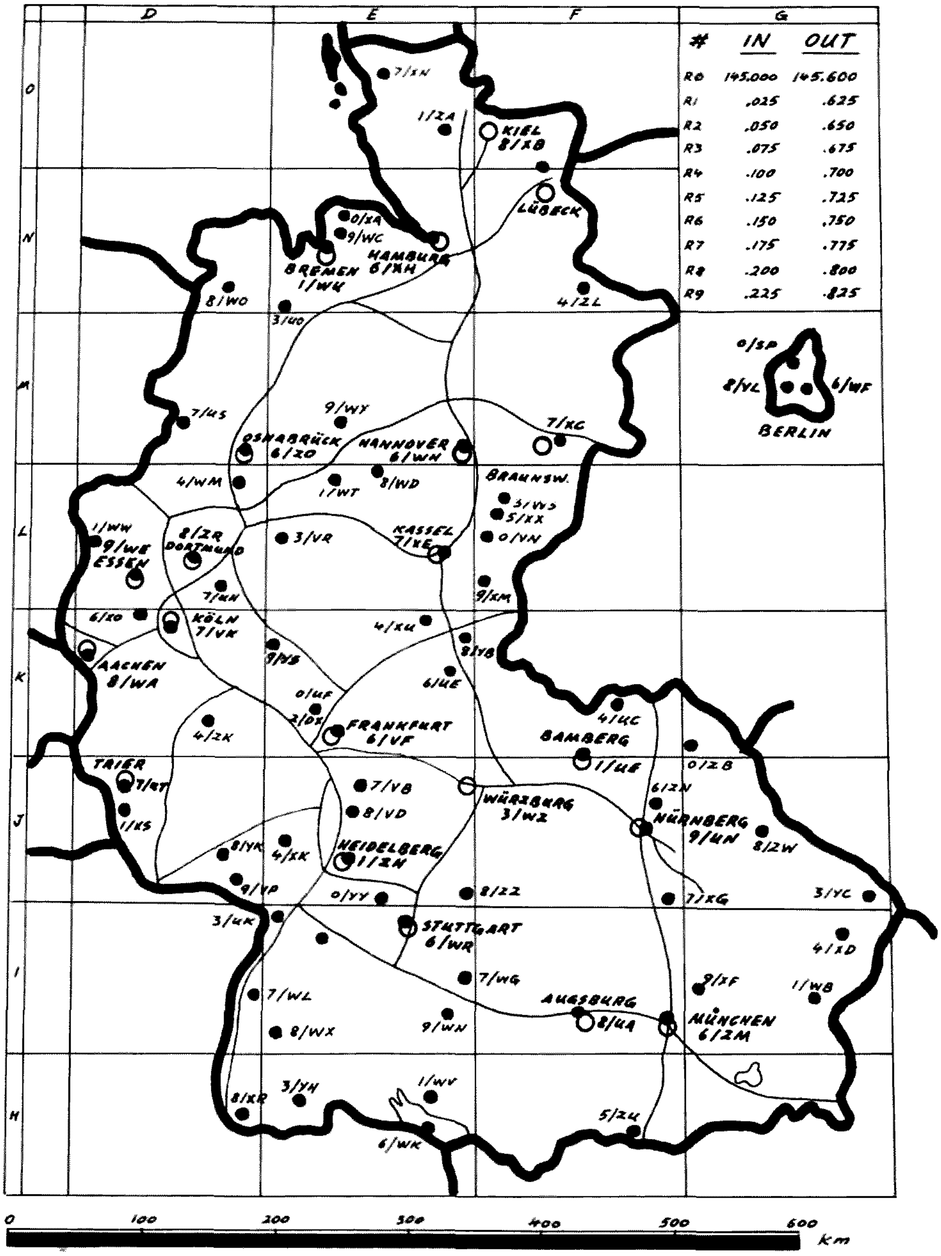

Fig. 1. Two meter repeaters in Germany.

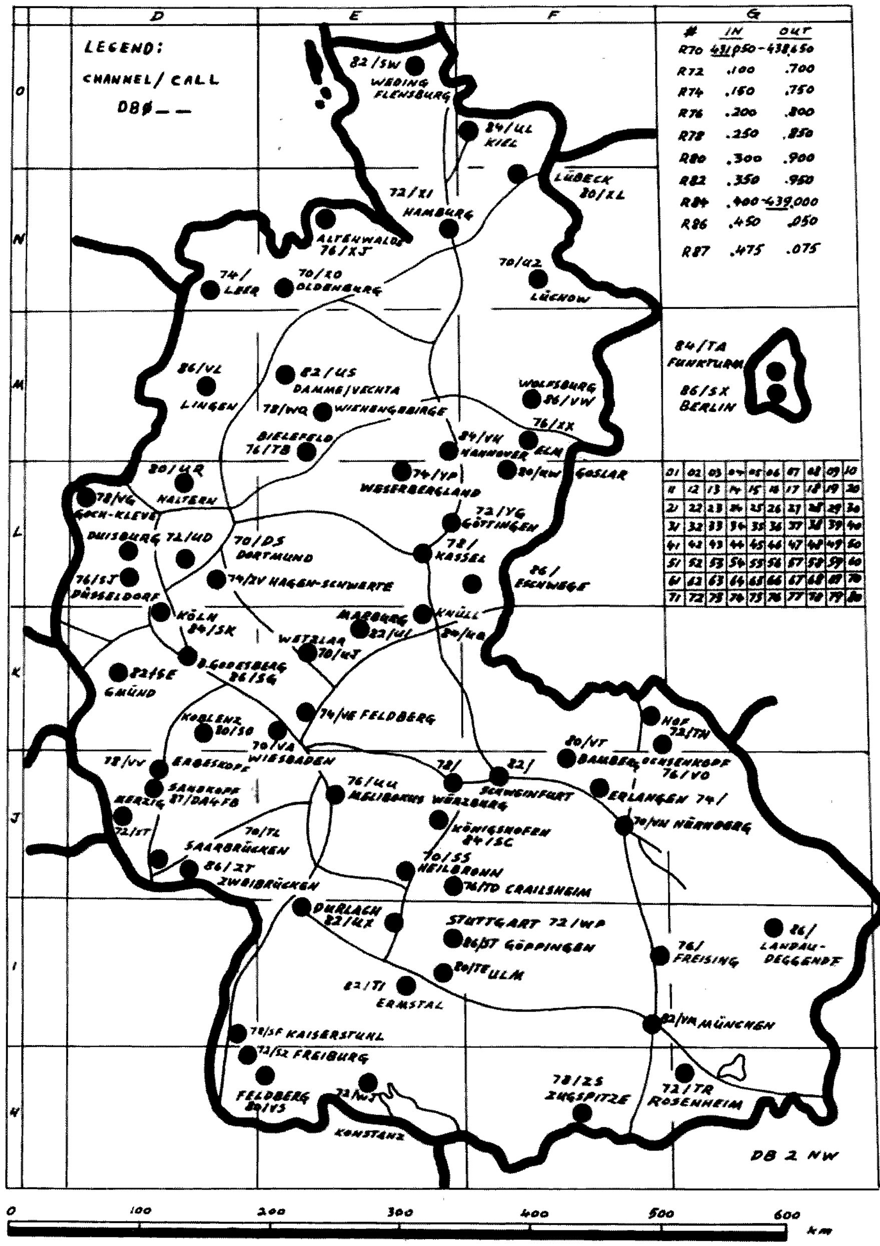

Fig. 2. 70 cm repeaters in Germany.

are ten two meter repeater channels allocated to about 77 active machines on a 25 kHz spacing, and with no oddball or reverse splits. Fig. 1 is a map of two meter FM repeaters in Germany. The 70 cm repeaters number 45 at present, and, although provision is made for the eventual use of 25 kHz spacing, present spacing is mainly 50 kHz. Fig. 2 shows the German 70 cm repeaters. All German repeaters operate on a dual entry of carrier squelch plus a 1750 Hz tone burst. No other entry tone burst frequency is allowed, and many commercial transceivers sold in the U.S. have a special German "G" version, which includes a tone burst circuit for this purpose. The DARC coordinates all repeater locations and frequencies, and the DBP will not process a license application for a repeater that has not been approved by the DARC. Some DARC standards for repeaters include a 4-5 second delay on transmitter turnoff, a 1-2 minute time-out on individual transmissions, and a 1-1.5 second delay between squelch off and time-out timer (TOT) reset, at which time a short audio beep called a "roger beep" is sounded to tell the repeater users that the TOT has reset. This last feature works wonders in discouraging tailgaters from excluding breakers and emergency traffic. In addition to FM repeaters, there are a few repeaters available for ATV and RTTY, plus some linear transponders. All German two meter repeaters are extremely busy. Unless he has an adequate command of the German language, the American ham in Germany will usually avoid the repeaters and operate on the simplex channels, with 145.550 MHz being the standard frequency adapted by the DA stations.

So far it would seem that the VHF/UHF scene is exclusively FM, but this is far from true. There is heavy use of two meter SSB, and it is not unusual to work Austria, Switzerland, Belgium, France, Luxembourg, Holland, or England on good days. Nor is it unusual to talk to a two meter station using a 15 Watt transceiver and a 40 to 88 element yagi array! Also, the Germans are heavily active on OSCAR and, in fact, operate a branch of AMSAT, AMSAT-DL, which furnished the mode "B" 70 cm to two meter transponder now in operation in OSCAR 7. In fact, there are more active mode B users in Europe than in the whole U.S.A.

There are some FM repeaters appearing on the 23 cm band now, and several groups are working with such high frequencies as 10.5 GHz microwave. But this is relatively specialized and beyond the scope of this article.

Those hams who aren't on the air talking may well be at their benches building a home brew project. Home brewing is very popular, especially at VHF and above, and there is a whole subgroup of hams devoted to this aspect. There is even a magazine, called *VHF Communications*, which is published in both German and English language versions four times a year and is devoted to home brew projects. The nice thing about this particular publication is that it offers as a service the complete availability of critical parts and printed circuit boards to duplicate any project that has

been published. German home brew equipment generally reflects a high standard of technical sophistication and construction technique excellence.

If you have a radio frequency interference problem, don't despair. The Bundespost has a large fleet of specially equipped radio test vans and friendly, helpful, proficient technicians who can come to you and evaluate your station and transmitted signal. If you are "clean," German law requires the owner of the TV, stereo, antenna preamplifier, etc., to fix his equipment by shielding, grounding, and filtering. Of course, if you are at fault, you can be required to install your own station low pass filters, grounding, etc., as may be required, plus obey license restrictions until you are clean, just as in the U.S.A.

If you like to meet your ham friends, look at the latest commercial equipment, or buy some parts or kits, have a dinner with music and a live dance band, you can do it all at a German hamfest. Just as in the U.S.A., these popular occasions come in all sizes, from large to small, ranging from national to local in scope. Not only are the German fests categorized by size, but they are also sometimes devoted to a particular interest group. Can you imagine a Dayton Hamfest devoted to exclusively VHF/UHF interests? In Germany, one such event that draws national attendance of VHF/UHF enthusiasts is held every autumn at Weinheim, and is quite a feast for those who like VHF/UHF FM, SSB, commercial and home brew equipment and antennas.

The national radio club, the DARC, boasts a membership of over 90% of Germany's 25,000 hams and offers a wide variety of services. The club's national magazine, *CQ-DL*, is published monthly with 80 pages and 30,000 copies. The club is organized into 19 districts, each of which can have up to 50 local clubs. The club magazine offers operating and legal news on the international, national, and local fronts, technical articles, etc., just like any ham magazine. If you think the new equipment reviews written by the American hams in American magazines are worthwhile, you should see the articles written by the DARC engineering staff after a checkout in the club's lab. One commercial Japanese all-mode two meter transceiver that got a one page review by an American magazine received an eleven page thoroughly technical review by the DARC!

Another service of the DARC is an international and national QSL bureau, which handles cards sent and received. Cards are processed from the club and its allied national QSL bureaus to the individual district clubs. One more service is a third party insurance policy for hams to cover damages; for example, it might cover damages caused by an antenna blowing down or falling onto a neighbor or his roof.

As mentioned earlier in the article, the DARC works extremely closely with the German government. What does all this cost? At first, the annual dues of 65 DM ($27) seem like a lot, but when you consider all the services available, as only partly mentioned above, it becomes much more reasonable.

Incidentally, U.S. hams stationed in Germany with the military are generously afforded reciprocity by the DARC as a courtesy, which means that the ham can defer receiving the German language *CQ-DL Magazine* and the insurance policy, and still use the full QSL bureau services through a local DARC club for only 11 DM ($4.60) a year. All it takes is 40 or more QSL cards sent out by U.S. postage rates to make the fixed charge look good, and it looks even better when you discover that, while in the U.S. a first class letter costs 13¢, in Germany a first class letter within the country costs 21¢, and international European mail from Germany costs 50¢ or more. Nonetheless, many American hams do pay the full dues and enjoy the full privileges of the DARC. You'd be surprised how well you can understand the German language ham magazine, even if you don't "spricht Deutsch," by looking at the pictures and catching key words in the text; after all, a dB or kHz in English is the same in German!

Speaking of clubs, the largest and most organized American club in Germany is the Wiesbaden Amateur Radio Club. This club is headquartered in Wiesbaden, Germany, has an international cast of members, but is heavily composed of Americans working in Germany. This ARRL affiliated club is associated with its DARC counterpart local club, and enjoys outstanding cooperation and rapport with the local German club and the DARC. Members come from over an hour's drive away to attend the monthly club meetings, and the club's activities include the only "Americanized" hamfest, held once each May in Germany, as a regular event. The hamfest is an excellent meeting place for hundreds of German and American hams, as well as those of several other nationalities. It's a real sight to see the German hams eating the club's food concession's barbecued hamburgers, while the American hams eat wurst and brotchen. The hamfest has a technical booth, where FM transceivers are checked for frequency, power, and deviation. Other fest features enjoyed by all

Frequency	Class A/B modes	Class C modes
3.5-3.8	A1, A2, A3, A3J, F1, F3	none
7.0-7.1	A1, A2, A3, A3J, F1, F3	none
14.0-14.35	A1, A2, A3, A3J, F1, F3	none
21.0-21.45	A1, A2, A3, A3J, F1, F3	none

87	431.475	439.075

Table 3. 70 cm FM band plan.

are the flea market, door prize raffle, and end-of-the-day flea market auction, with the latter being especially novel and enjoyed by the German hams.

Also, of course, the club offers code and theory classes during the year. Since elimination of the mail exams, it has become harder to get new hams or upgrade licenses, but the FCC has been very helpful by working with the authorities to allow an examiner to come to Germany twice a year to give commercial and amateur exams. If you want to talk to a club member, you'll find him on 145.550 MHz FM or on the club's repeater, DA4FB. This open repeater is the only one in Germany that has a license granted to an American-backed club, and operates on channel 87, as per Table 3. So, by all means, bring along your two meter and 70 cm FM rigs when you come to Germany.

As you can see, hamming in Germany has a lot to offer. Perhaps this article will allow you to have a more meaningful and interesting rag chew with the next "D" prefix station you talk to, or, if you are coming to Germany to visit or work, you will be better prepared to enjoy your hobby more fully. The hams in Germany and Europe are very friendly and helpful, and you are sure to enjoy your next QSO or visit.

I've had the pleasure of living and hamming in Germany for three years, and would like to take this opportunity to express my deep appreciation to all the hams in Germany, the DARC, and the Wiesbaden ARC, for making it so much fun and for helping me to see another aspect of my hobby. A special thanks to Jean Binet DCØHO/FØAOB and to Herb Brasington DA1KD/WB4EWX for their help and encouragement in the writing of this article. Auf Wiedersehen! ■

The DA4FB Story

-- American repeater in Germany

How do you draw together amateurs who are spread over a large geographical area (4700 square miles) and provide for reliable communications among them? One obvious solution to this problem is the installation of an FM repeater. But, when you consider that the geographical area of concern is in the Federal Republic of Germany, and that the majority of the amateurs are Americans, the solution to the problem is a little more complex.

Members of the US Wiesbaden Amateur Radio Club (USWARC), a large group of amateurs composed heavily of Americans living and working in West Germany, began discussing this problem in May, 1976. A repeater committee was formed, and various members of the club and committee were tasked to begin to look for a suitable site, secure equipment, and apply for the station license.

The area of desired coverage was so large that a central location for the repeater was necessary. The terrain consists mainly of rolling hills, and is divided almost in half by a range of mountains that runs northeast/southwest through the area. Jerry Stewart K5CFQ/DA1HZ was able to secure permission to install the proposed repeater at a military communications site near the center of the area. The site is on a 2300-foot mountain, has a 300-foot microwave tower, is manned 24 hours a day, and has emergency backup generators. What more could be asked for?

Preliminary negotiations were initiated with Deutschland Amateur Radio Club (DARC) officials for the authority to install and operate a repeater. The FTZ division of the Deutsche Bundespost (DBP, the German equivalent of the FCC) will issue a license for a repeater only if the license application has been coordinated with

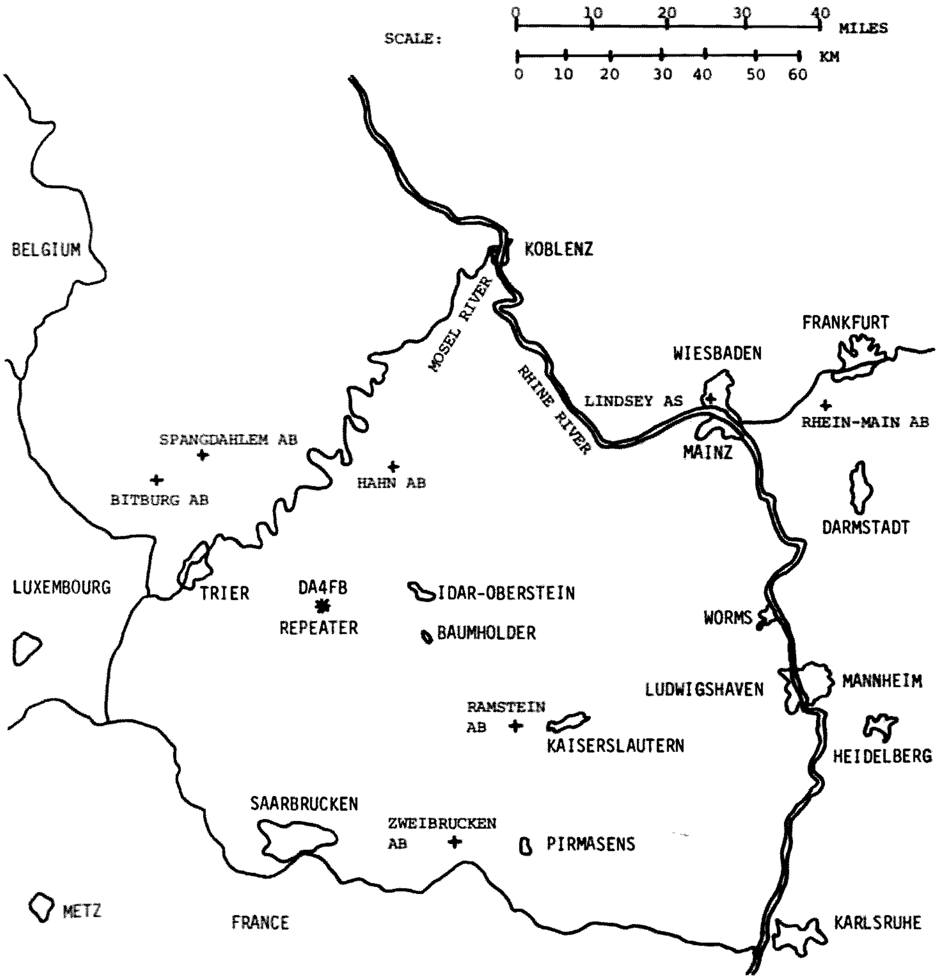

Fig. 1. Area of coverage of DA4FB 70 cm repeater, with major cities and USAF military installations indicated. The antenna is at a height of 800 meters (2624 feet), and has a cardioid pattern oriented toward Frankfurt.

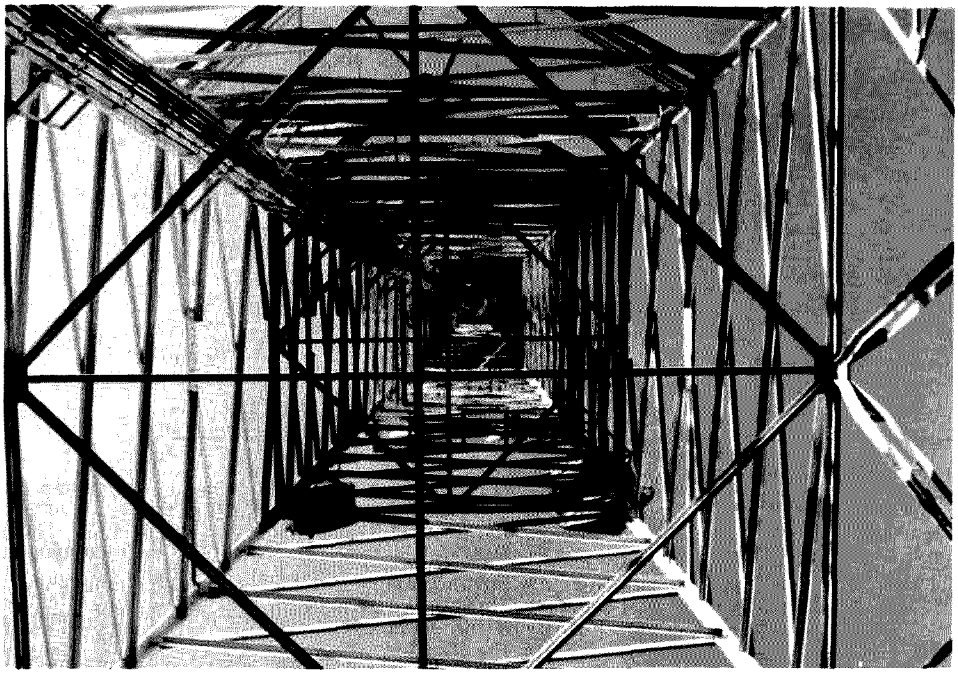
the DARC. The DARC analyzes the application and insures sufficient separation between repeaters (both in frequency and distance) before giving the OK to the FTZ to issue the license. The DARC makes the frequency assignments and tells the FTZ what frequency pair is to be on the license. As you can see, the DARC is a very powerful organization. But their power is well directed, and repeater wars are almost nonexistent in Germany.



DARC officials indicated that the 2 meter band was extremely crowded and that they could only agree to a repeater in operation on the 70 centimeter band (430-440 MHz). The USWARC discussed this proposal and agreed that a 70 cm repeater was acceptable.

The search for equipment then began in earnest. About the only rig available at first was the VHF Engineering 70 cm repeater. The projected cost of the repeater, coax, antenna, control logic, duplexer and miscellaneous parts soon grew to over $1000, and the repeater committee started looking for fundraising projects.

Some of the USWARC members are associated with Motorola GmbH, and high level corporate management was informed of the club's repeater project. Soon, a rebuilt 70 cm MOTRAC repeater, complete with control logic, duplexer, and 350 feet of 7/8" foam coax, was donated to the club by the corporation!

By this time, eight months had passed since first discussion of the project, and the committee was ready to install the repeater antenna. A CushCraft 4-pole phased array was purchased, and it was decided that the cardioid pattern should be directed toward Frankfurt (as that city was the farthest distance from the site in the area of desired coverage). Installation was planned for the first weekend in December. (Why do all complex antenna projects have to be accomplished in the winter?) The weather cooperated, and the weekend turned out to be clear and cold. Normally, German winter weather would prevent anyone from seeing the top of the tower from ground level. The job was time-consuming, with the installation of the heavy coax being the major back-breaker. The antenna was placed about 5 feet below the top of the tower, a definitely impressive location with a commanding view of the countryside.

The repeater was installed in a new upright cabinet, and work began on the control logic to conform with DARC standards. At about the same time, the repeater frequency pair was changed by the DARC due to complaints to the DBP by a repeater group who had previously operated a machine on the frequency pair assigned to the USWARC in the same general location as the club's repeater site. A new pair on standard channel R87 was assigned to the club, with input on 431.475 MHz and output on 439.075 MHz. This provided 25 kHz separation from the next adjacent channel (R86) and is the first such channel assignment in Germany. New frequency elements were purchased for the machine, and work continued.

Finally, all the modifications were complete and the repeater was tuned and adjusted for proper operation. The only remaining items were the repeater license and correct programming of the ID unit, which is a little tough without the correct callsign. The wait for the license seemed eternal, and was due to slight confusion over what the correct licensing office was, since the club, trustee, and repeater were in different DBP administrative areas. This was cleared up, and in the third week of March, 1977, the license was issued with the callsign DA4FB. This is another "first," as all other repeater callsigns in Germany have DBØ prefixes. The DA prefix simply reflects the American club's operation under the German-American reciprocal licensing agreement.

The ID unit was programmed, and the machine went into test operation for a week before being transported to the site. On April 9, 1977, the repeater was installed on-site, and DA4FB became the first American-sponsored repeater to be licensed and in operation in the Federal Republic of Germany.

The repeater system was designed to give base station to base station coverage over most of the area depicted in Fig. 1. It was soon found that coverage was better than that planned for. Solid mobile operations are possible within about 30-40 miles of the repeater site. A five Watt base station with an eleven element beam is able to fully quiet the repeater receiver from Rhein-Main Air Base near Frankfurt, a distance of 72 miles from the site. A mobile station using a ten Watt transceiver and a 5 dB gain mobile antenna has copied the repeater signal with full quieting in the city of Heidelberg, a distance of 75 miles. Occasionally, a QSO will be conducted with a station outside of the depicted area. One station, DC5NB, located in Aschaffenburg, is a regular on the repeater. He is 97 miles from the site, and uses two 91-element yagis: one for transmit and one for receive. (The Europeans are big on VHF, UHF, and microwave work.)

Many American hams reside in the coverage area, but not too many are active on the 70 cm band. Many US Army installations and all major USAF installations in Germany are within range of the repeater. Kaiserslautern boasts the largest American community outside the US, with over 50,000 Americans. *All* hams are invited to use the open repeater and also join in the activities of the USWARC. If any further information is needed about the club or the repeater, contact the club vice president at the following address: Jean Binet DCØHO/FØOAB, In den Haferwiesen #30, 6506 Nackenheim, West Germany.

Many of the club members participated in this project and, without everyone working together, the job would have taken much longer and probably would not have enjoyed such success. The following is a list of the hams who devoted their time and energy to the USWARC repeater project: Mike Baker W8CM/DA1BM, Carl Beckenbach WA1LHW/DA1TT, Tex Bell WD8BGA/DA1BO, Jean Binet FØOAB/DCØHO, Herb Brasington WB4EWX/DA1KD, Jerry Cole WA7YMR/DA1JC, Chuck Elquist W6JIF/DA1BZ, Ed Goldsby W3JKL/DA1UC, Terry Huston WA8RYC/DA1TH, Gerhardt Pless DC8CX, Joe Roman WB7CCK/DJØNA, Jerry Stewart K5CFQ/DA1HZ, John Stohel WB7CVU/DA1AY.

Special thanks are due to Mike Baker, who was the design engineer, mastermind, and driving force for the whole project. Without the multi-linguistic talents of Jean Binet and Carl Beckenbach, the liaison work with the DARC and the DBP would have been difficult indeed. The USWARC would also like to express its unfailing gratitude to Motorola GmbH for its complete support of the repeater project. ■

Decode Morse

-- with an 8080

Why should you want to read another article on Morse decoding? I could tell you that this was the ultimate program (which it isn't), or that I have invented a new technique (I haven't). In fact, there is nothing tremendously novel about the material presented in this article. However, you will read about a completely general decoder algorithm which can be implemented on any microcomputer system. For those of you with an 8080-based system, a full program listing of the algorithm is included as an example.

My fascination with automatic decoding was fostered by the introduction of the first microprocessors. Up until then, I had considered the project too inflexible, from a hardware point of view. The microcomputer concept was appealing because of the easy way in which changes in the system could be implemented. I must admit that, from the very beginning, the problem of computer-generated Morse code was not as interesting a project, since it is relatively straightforward. Hence, this article will not be concerned with that aspect of a system.

The concepts used in this decoder are from many sources, including my own work. The magazine articles which I have studied are listed at the end of this article. Most authors start their presentation with a list of features and a description of the method for distinguishing dots from dashes. This is a good approach, so I will do likewise.

Variable	Description
TIME	Elapsed time counter (14 bits). If overflow occurs(>14 bits), time is set to large value.
DD	Dot-dash time(≈15 bits). Value is calculated in Dot and Dash routine.
LS	Letter-space time(≈15 bits).
STAT	Main status register: Bit 7 Key status = 1 if key down 6 DD Flag = 1 if TIME DD 5 LS Flag = 1 if TIME LS 4 Sidetone 3 --- 2, 1, 0 Debounce counter
STAT2	Secondary status register Bits 5-0 are the CRLF counter
CODE	Code register, used for storage of incoming dots and dashes. For dots CODE = CODE * 2, for dashes CODE = (CODE * 2) + 1. Bits 5-0 are used.
CPTR	Column pointer, used for automatic CRLF function. Six bits or more may be required for storage.

Table 1. Description of variable storage requirements.

Decoder Features

My idea of desirable features are those that minimize the external hardware requirements for normal operation. There will always be special cases, which need advanced hardware for error-free operation.

Here is the list of features incorporated in my algorithm:

1. All program timing is done with software delays.
2. A sidetone is generated for monitoring the operation of the decoder.
3. An automatic carriage return/line feed (CRLF) sequence is generated.
4. The code input is debounced for reliable performance from a variety of sources.
5. The speed range is from at least 5 wpm to about 50 wpm.
6. The I/O routines that must be supplied by the user easily patch into the program.

The method used for interpreting dots, dashes, letters, and spaces is adapted from Petit's original article. Briefly, the rules are as follows:

1. If the key-down interval is ⩾ DD (the last dot-dash time, explained later), then the present element is a dash; otherwise, it is a dot.
2. If the key-up interval is ⩾ LS (the last letter-space time), then a character has been completely received and should be processed.
3. If the key-up interval is ⩾ 2LS, then a word has been completed.

Assuming a dot has been received, by rule 1, then DD is set to twice the duration of this dot. For dashes, a more complicated set of calculations is performed. In hand-sent code, which is most difficult for the computer, a tendency for variations in dash duration is common. This usually occurs at the end of words and often precedes a long pause during which the operator collects his thoughts. Therefore, I decided to average the received dash interval with the last received element. The averaging is accomplished by dividing the duration of the present dash by two and, then, adding the last value of DD. This is the LS value referred to in the above rules. By dividing by two once more, the new DD value is calculated. Two features result from this set of manipulations: (1) The letter-space decisions are heavily weighted by the duration of dashes, and (2) the effect of excessively long dash intervals is reduced. These seem like desirable traits, and yet do not add much complexity to the algorithm.

Software

The algorithm which has been partially discussed is presented in flowchart form in Figs. 1 and 2. A generalized symbolic approach, similar to BASIC statement

structure, is used, except for the status subroutine. This routine will be discussed in detail, since it is the cornerstone of the decoder.

The main routine is presented in Fig. 1. All the operations necessary for translating the received code into text form can be easily identified. Starting from the top and working down, the first step is program initialization, followed by a routine for printing a space.

After the space is printed, a key-down input causes the program to go to the Down routine. When the key returns to the up state, a branch to the Dot or Dash routine occurs. Within each routine, calculations for updating DD and LS, along with storage of the received elements, are made.

While the input continues in the key-up condition, the elapsed time is measured in the Wait routine. If an end of character is detected before the next down state, a transition to the Decode and Print routine is made. After printing the character, another wait loop is entered. If it times out, then a word has been received. Before printing a space, a check as to whether or not the algorithm should stop is performed. Usually the program will continue by printing a space.

Looking at the program subroutines presented in Fig. 2 will illustrate further details of the software. Four internal subroutines are called by the main program routines. These are (1) Status, (2) Print, (3) Decode, and (4) Delay. The Delay subroutine times out after 1 ms has elapsed. Obviously, this function will require different initialization, depending on the microcomputer used. The Decode subroutine performs the actual conversion from the dots and dashes, stored as a unique digital pattern, to the ASCII character representation.

In this algorithm, an automatic carriage return and line feed sequence is initiated by the first space character occurring after the 55th column. This is handled in the first section of the Print subroutine. Normally, the character is printed by calling a user-defined subroutine. However, if the CRLF sequence must be printed, the CR is immediately output, and a counter is set up for delaying the printout of a line feed.

The Status subroutine is the most complicated portion of software in the decoder. Note that all the timing in the main routine is determined by this subroutine. A call to the Delay routine, which returns after 1 ms, is the first action taken. Then the possibility that a line feed must be printed is tested and appropriate actions taken. Next, the key input (or receiver) is sampled for an up or down state. If a new state is detected, the debounce counter is decremented. A zero debounce count signifies that, in fact, the key has changed state and causes the key status to be updated. Otherwise, the debounce count is stored and the routine continues. Now the user-written routine for outputting the sidetone value is called, and, then, the elapsed time counter is incremented (checking for overflow). Lastly, the LS and DD flags, which indicate whether the time is ≥ LS or DD, are stored. These flags are easily checked in the main routine's decision-making process.

Details, Details . . .

Many flags, counters, pointers, and registers have been mentioned in the algorithm description. These are summarized in Table 1. In the 8080 listing presented, they occupy ten bytes of memory. Further explanation of the characteristics of these variables will complete the description of the algorithm.

The TIME counter is incremented as each pass through the Status subroutine is completed. An overflow condition is checked, and the variable is set to a large value, if

Table 2. ASCII look-up table for character decoding. The hex number corresponds to the value of the code counter.

necessary. Both the DD and LS counters have been previously described, and they should be about one bit larger than the TIME counter. The main status register, STAT, holds the flags and single bit variables. There is nothing unique about its organization, except where it might simplify programming. A secondary status register, STAT2, is used for counting the delay necessary after a carriage return and before the line feed is issued. This feature may only be necessary for mechanical printers.

The CODE register is used for storage of the incoming dots and dashes. It is initialized to a value of 1 before each character is received. For a dot, the value is doubled; for a dash, it is doubled and then incremented by one. This is the simplest technique for storage of the elements, which results in a 64-location ASCII look-up table. To make sure that the contents of the counter are less than 64, an overflow condition must be checked after each entry. If an overflow occurs, the value is divided by two, and the algorithm continues. In using such a simple method, a sacrifice is made in not uniquely decoding a few special characters. For example, an error is decoded as the number five. The corresponding ASCII look-up table is presented in Table 2.

For the automatic CRLF feature, a pointer for the column position must be kept. This is the function of CPTR. In my version of the algorithm, I check for a value greater than 55, at which time the CRLF sequence is initiated.

Subroutines

There are two kinds of subroutines necessary for proper operation of the algorithm. The first kind, the main program subroutines, are well-defined for any microprocessor chosen for implementation of the decoder. The second type, user-supplied subroutines, will vary from one particular equipment setup to another. A few more comments concerning the first type will be made before attention is focused on the user-supplied subroutines.

There are several subtle aspects concerning the Status subroutine. In Fig. 1, the subroutine is called repeatedly while in the down state. The rate at which this loop is executed defines the frequency of the sidetone output. If all the possible paths through the Status subroutine are not matched for execution time, an instability in the sidetone output will result. A difference of only a few machine instructions can be detected by the ear. This problem can be handled by whatever method is easiest for the microcomputer used. In the 8080 example program, 13 bytes of extra jump instructions are used for the timing equalization.

The second point worth mentioning is the comparison of the TIME counter with LS and DD. Since these are 16-bit unsigned values, you will have to be careful if it is necessary to break it up into 8-bit comparisons. Beware of your microcomputer's 2's complement arithmetic!

The user-supplied I/O subroutine requirements are summarized in Table 3. There are four routines, which are concerned with printing a character, sampling the key input, generating the sidetone, and stopping execution of the program. All these functions require interfacing with your particular computer configuration.

As examples, the subroutines that I used in my 8080 program will be described. First, notice that they are linked to the main routines through an I/O patch table, which follows the Delay subroutine. This makes it possible to call the user subroutines from one section of code. There is no need to hunt through the listing for the subroutine calls when supplying your customized I/O. The Cout subroutine sends the ASCII character to the UART or display device, after checking if the device is ready. For sampling the key

COUT	Called by the Print subroutine. A character is passed, the UART status is checked, and the character is sent to the display device.
SKEY	An input line is tested for the key up or down state. The appropriate result is returned to the status subroutine.
CONT	The main program can be stopped by an appropriate hardware input which is checked by this routine.
TONE	Called by the status subroutine. If the key is down, toggle the sidetone output line and save value in STAT register. If key is up do nothing.

Table 3. User I/O subroutine specifications.

input, the Skey subroutine reads an input line and then returns with an appropriate flag. The Cont subroutine reads a status line and then either returns to the main program or stops execution. (Instead of stopping execution, a branch to another program would be possible.) A sidetone is generated by the Tone subroutine. The key state is checked, and, if the key is up, a return to Status occurs. Otherwise, the last sidetone value is toggled, output, and saved for the next iteration. This generates a square wave with a period equal to two passes through the Status subroutine.

User Modifications

Perhaps one of the most interesting aspects of playing with computer programs is making changes which reflect how you feel the program should have been written. Since I suspect many of you are already considering changes to this program, let me suggest a few first.

One possible modification would be to calculate a smaller value for LS (but not for DD). When copying the 18 wpm code bulletins from W1AW, I set LS = DD = [(TIME/2) + DD]/2, which is a simple change. Since the original LS value calculated in the algorithm is approximately equal to the average dash, this would suggest that Petit's rule, of using 3/4 of the dash, might be a good compromise.

Other possible changes include timing modifications and altering the line length for your particular terminal. Timing changes would be possible in the CRLF sequence (i.e., change CRDLY) or in the 1 ms Delay subroutine. By changing the duration of the delay, the sampling rate and sidetone frequency would be affected. If your display device doesn't accommodate at least 55 characters per line, this value could be changed (in the Print subroutine).

The four user-supplied subroutines are obvious places where you may require different code than in my examples. This could be as simple as changing port assignments.

Hardware

Simple hardware interfaces were built for the initial testing of the decoder. These are illustrated in Fig. 3 and consist of output and input circuitry.

The sidetone output is a square wave, which can easily drive a speaker using an emitter follower. The NPN transistor can be any power transistor out of your junk box. The interface for driving your display device is probably available from other projects, so I won't make any comments concerning this subject.

For receiving code, two simple circuits will get you going. Initially, I would suggest hooking up your favorite key or keyer to the code input line; a 1k pull-up resistor may be necessary. After the operation of the algorithm has been checked, it is time to connect a receiver to the computer.

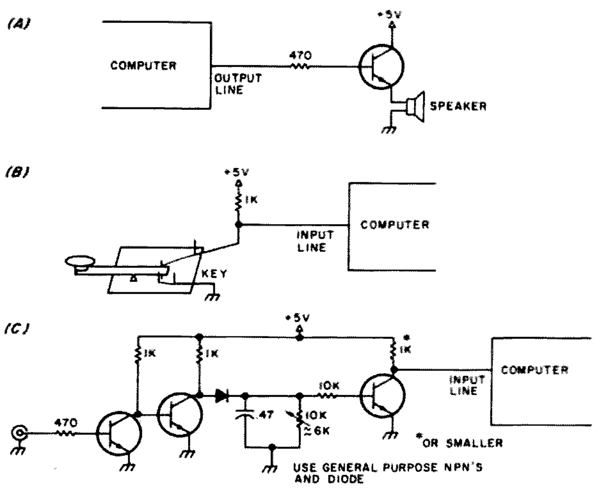

Fig. 3. Simple hardware interfaces. (a) Speaker connections; (b) key input; (c) receiver audio adapter.

I know of no easily constructed optimum interface between a receiver and a computer. Many ideas have been proposed, including narrow pass band filters and phase locked loops. These approaches are not appropriate for the goal of minimizing external hardware under normal conditions. Instead, I will assume you have a good receiver with an adequate CW filter. Connecting the circuit of Fig. 3(c) will provide satisfactory operation in most cases. The audio input is amplified (only about 2 V p-p input is required) and then applied to a peak detector, which follows the envelope of the received signal. The variable resistor can be used for adjusting the decay time constant, or a fixed value can be substituted. The output stage operates as a switch for driving the computer. By monitoring the sidetone output, the input level can be easily adjusted for any signal.

The Next Step Is Yours

With the information presented in this article, you should be able to program a computer for Morse code reception. If nothing else, this is an impressive demonstration for your friends. I hope you will not restrict your efforts solely to the ideas presented here, but will continue with further experimentation on your own.

Possible areas of experimentation include a different LS calculation, a BASIC program implementation, or matched filtering for the receiver interface. With a fast BASIC interpreter, most of the algorithm could be written directly from the flowcharts. However, the Status subroutine would be best left as a machine language program. Using some of the newly-available tapped analog delay lines (such as the Reticon TAD-32), an adaptive matched filter for optimum detection may be possible.

As a final challenge, consider how it might be possible to implement the decoder using one of the new single-chip microprocessors. The 8080 listing which follows is less than 512 bytes!

Thanks

I would like to thank the authors for writing the articles which are listed under references. A special thanks goes to Steve Belter WB9SGP, for his suggestions and support.

I will be happy to correspond directly with anyone on this subject; please include an SASE. ■

Futureshot

-- just around the corner

Fred Thompson hurried through the shopping mall. His watch showed him that it was 8:57, and he knew that Harry closed the doors promptly at 9 pm. Harry's Computer Store was the largest in the city, and Fred was sure Harry would have the integrated circuit he needed.

"Whoa," Fred said, "got time for a paying customer, don't you?"

"Sure," Harry backed away from the door he was about to close and chuckled, "glad to take your money. What do you need?"

"Program chip." Fred answered. "Got a French language course?"

"Check the wall unit over there. We don't get too much call for those, so it's probably down in the bottom cabinets someplace."

Fred keyed "French language" into the wall mini-terminal. The liquid crystal display listed two brand names.

"Hey, you've got two kinds in stock."

"Better check," Harry advised, "one might use two chips."

Fred asked the computer for a compare and contrast. Sure enough, one program, which gave complete branching and learning reinforcement, used two chips. One chip was the program and a file. The other was just a vocabulary file of four megabits. The price differential was only about 30%. Fred touched the listing for the two-chip version to indicate his choice. A green LED came on over the handle of the bottom drawer. He opened the drawer and took out one of the bags from the cubbyhole indicated by a photoluminescent panel.

"What, no servomechanism to drop it in front of the point of sale terminal?" Fred chided.

"I told you we don't get much call for that program," Harry responded. "Gotta save the gadgets for the big sellers — private secretary and the like."

"Been selling a lot of the private secretary?"

"Oh yeah, been selling a lot of the vocal interfaces, too, both male and female voices."

"I didn't buy the talk feature. I think it's great telling the machine what to do without any backtalk."

"Yeah, they say the darnedest things. Don't know what some of those programmers are thinking of sometimes. Well, anything else? We called up a back file of 'Star Trek' on the TV tonight, and I want to get home to make sure it gets recorded okay."

"Captain Kirk still chasing Klingons, eh? How much do I owe you?"

"With state and federal sales tax, twenty dollars and forty cents. Want to use my terminal or have you got your remote toy with you? Last ham radio operator I had in here insisted on using his homemade handi-term. Took him three tries, and he wound up crediting me with a hundred dollars too much."

"Never fear, mine works!" Fred said. He pulled back his shirt sleeve to reveal what appeared to be an odd-shaped calculator, with a rubber stick attached. "I don't mind an exterior antenna. Gives me great coverage through the local repeater," he said. As he talked, he composed a digital message that consisted of his amateur radio callsign, Harry's account number, his account number, the date (November 2, 1985), and the amount. He pressed the transmit button, and Harry's counter terminal registered the correct transfer on its readout. "Hah, see!" he said proudly.

"How long do you figure till everybody has one of those?" Harry asked.

"Probably never, except for a few kinds of salesmen. It's just a toy, like you said. Well, thanks a lot."

"Thank you. We've got Spanish, Russian, any kind of language course you want."

"This is for my daughter's French class. A few of the kids don't have access to a microcomputer at home yet, so I thought I'd let her take a CPU to school in her book bag and use the school's peripherals."

"If I can help, let me know. Night, Fred."

"End," Fred responded in BASIC.

Fred got back to his car and saw that the parking meter had almost run out. "Boy, a dollar sure doesn't buy much time anymore," he thought.

On the way home, the message indicator on his amateur radio rig was blank, so he put out an "available" or CQ message. Almost immediately the display showed a response and the callsign K9KIC. Fred knew that this was the call of a young man named John, who lived nearby. They had never met, but they had shared many interesting conversations over the radio. At the next stop sign, Fred saw that John wanted to switch over to voice transmission. He picked up a pencil-thin microphone which was connected to the radio by a piece of slender plastic line. "Hey, John, what brings you on this band now? Did the amateur radio satellite fall out of synchronous orbit?"

"No," came the voice through the solid state speaker, "Murphy has struck, and I need some technical help."

"Well, tell me what you've got, and I'll make one of my educated guesses," Fred responded.

"You were with me when I bought that old Z-80 CPU at the swap meet. I've got it up and running on an antenna-aiming program for the Russian amateur radio satellites. Everything goes fine

until I actually hook up the azimuth and elevation rotators. The first time it changes the azimuth, everything stops. Whaddya think?"

"Well, my young lad, my educated guess is spikes."

"Spikes! But there are lots of capacitors everywhere, and the power supply just has tons of farads hanging on it."

"The power supply, yes, but you are about to learn one of the main reasons why computer designers, radio designers, and almost everyone who pushes an electron has gone to fiber optics for signal circuits. These program chips that I just bought are a good example – two power connectors and ten optical signal ports each. Sure makes it nice."

"Okay, Fred, I can see I'm going to have to listen to one of your lectures, if I want to get my antenna pointed. Go ahead."

"You are aware that wires used to be used for carrying things other than power?"

"They still carry rf, Fred."

"Hrumph. That's power, too. Anyway, all the signal leads in computers, radios, phonographs, and everything else once were metallic. The time and money we used to spend eliminating hum, rf interference, and all the other kinds of unwanted signals were amazing. Bypass capacitors by the bushel, special circuit board and cabinet designs, tons of sheet metal. Then, about '79, the use of fiber optics for carrying signals really came of age. Practical microcomputers were only a few years older, so the marriage was a natural. Their use in radios and TVs was spurred along by federal legislation aimed at reducing TV interference, so you just don't find many of the metallic signal bus systems anymore."

"Well, I did."

"Right, and now we have to reinvent a few old tricks. I think that every time the relay in that old antenna rotator control unit of yours clicks, a big spike is sent back to the computer over the control wires. That spike drives the microprocessor crazy. Do you have any old discrete optoisolators in your junk box?"

"I'm not really sure what they are."

"Nowadays they are just a part of many chips, but basically, they relay a control signal, via light, to get rid of any spikes that might be introduced. You come on over tomorrow, and I'll see if I can find a reference that tells us how to use them. Here, I've keyed up my address. Come over about 10 am."

"Okay! Thanks a bunch, Fred. See you then."

As he signed off from his contact, Fred pulled into his carport. He put the tires of his car into the wide grooves in the composite floor and stopped when a light glowed on the dashboard. Beneath the car, twin spring contacts were already recharging the car's battery. He opened the front door of the house by punching a four digit sequence on the lock.

"Hi, anybody home?" he asked.

"We're downstairs," a female voice answered.

He went down into the main portion of the house, which was below the level of the surrounding ground. This arrangement gave both superb insulation and a nice landscape. The family room was dark, with the skylight in the clear mode to give an undistorted view of the night sky.

"Did you just get off work, dear?" he asked. His eyes were still adjusting to the darkened room.

"Yes, we had another one of those late conferences – more decisions and options," his wife replied.

"I'm glad you're home, Daddy," his daughter Jeanne interjected. "This is one of the first tries for our class project. Mother may understand stocks and bonds, but laser communications are too much for her."

"Oh great," Fred said, "I had forgotten it was tonight. We must not have entered it into the secretary. Where is the target?"

"The computer says that Orbiting Base I is due to pass over in about 15 minutes. We are going to try hitting it with a laser from the roof of the school. We want to use the communications mirror on the Orbiting Base to bounce a signal. I've got this laser detector set up here, and Sue and Billy each have one, too. It's not very precise, but we can show the principles involved."

"That would be a pretty fair accomplishment," Fred replied. "The military and some hams have been using the satellite mirror incremented light element system for some time, but if you kids can bounce off the Orbiting Base, you can get some good communications and good tracking data at the same time." Fred walked over to the small computer terminal hanging on the wall of the family room. He touched a sensitive square on the top of the visual display and said, "Print time; Print Orbiting Base time; Print difference; Run."

Immediately the solid state display showed:

2137:20
2143:33
6:13

"You going to work through the skylight?" he asked his daughter.

"Yes, I don't think we'll lose very much, since it's in the clear mode."

"If you two will excuse me," his wife said, "I'm going to take a bath. Secretary," she said, touching the computer terminal. The screen printed "READY" above the time numerals still on its face. This indicated that the secretary program was ready for use. "Bath; Hot; Full; Run," she said. "Isn't science wonderful!?" she chided, after taking her hand off the computer's touch spot. "Let me know when you talk to the woman in the moon."

"Ouch," Fred said, "give 'em females on the Orbiting Base, and they want the whole moon."

"Just our fair share, Daddy," Jeanne laughed.

The minutes and seconds displayed on the computer terminal went by swiftly. The Orbiting Base passed overhead. The laser detector was operating at its highest gain, but nothing was heard. Ten minutes after the direct overhead pass, the phone buzzed and Jeanne hurried to answer it.

"No, Billy, we didn't hear anything. What? You did. I know I had everything set up right. OK, we'll have to check it out tomorrow."

"They heard the bounced signal?"

"Yes, but without all three results, we can't get any accurate position data to write up. It isn't just enough to receive a signal; we have to be able to show good tracking data, too, if we are going to get a good grade on the project."

"Boy, high school science projects sure have changed," Fred mused. "Let's see if there is anything wrong with your receiver that an old technician can recognize."

Fred placed the equipment in self-test and made all of the checks with no discrepancies apparent. Opening the small cabinet revealed only two lumps coated with protective material. One was the entire detector and amplifier, and the other was the power supply. "Not an adjustment anyplace; besides, everything checks out okay."

"Thanks anyway, Daddy. At least I know I had it turned on and pointed the right way. The Orbiting Base will be over again tomorrow night. Maybe we can get a new receiver by then."

Later, as the house quieted down for the night, Fred addressed the computer again. "House; Status; Run." A floor plan of the house appeared. All doors and windows were shown in green, indicating they were

locked. Below the diagram, a row of numbers began to appear on the screen. They showed the temperature of the water in the solar heaters, the output of the wind generator, and the amount of power that had been drawn from the commercial mains to supplement the wind generator over the past 24 hours. The temperature in the various rooms and other factors, such as circulating air flow, were also shown. Security systems, fire detection, and environmental control were all under the control of the home computer system while the family slept.

The next morning found Fred hard at "work." Actually, he went into the office less and less each year. The marriage of cheap data processing with high quality communications interconnections allowed many people to do a great deal of their work at home. As a lead design engineer, Fred had ties, via telephone lines, to the five design engineers in his group. They were able to exchange ideas, diagrams, and comments through their computer terminals at home. They could confer individually, or as a group.

The "smart" terminals they were using contained powerful microprocessors and were actually stand-alone computers. They could work individually, in concert with other smart terminals, or as an extension of the central "big memory" operated by Fred's company. The savings in real estate and overhead more than paid for the cost of the additional communications circuits. Many businesses still required the personal touch. But those that could were encouraging their people to work at home. Fred's wife was at "work" in another part of the house. Their breaks were frequent, and their family life was quite strong.

At a little before 10 am, the secretarial program in Fred's computer printed out "K9KIC COMING TO VISIT AT 10 AM."

A few minutes later, the doorbell rang. The young man he admitted was quite different from the bookish boy Fred had expected to see. John was tall and athletic. He held out his hand and said, "Hi, I'm K9KIC."

"Come in," Fred said. "I've got an optoisolator on my desk."

They discussed optoelectronics, the good old days of ham radio, and several other topics. Fred was just about to relate how he had changed over his old receiver to fiber optic elements, when his daughter walked in.

"Hi, Dad, can you help me for a minute?" She was weighted down with various pieces of her laser project. "Oh, I'm sorry. I didn't know you had company."

"Jeanne, this is John, one of my ham radio buddies. John, my daughter Jeanne."

"Say, isn't that a laser detector?" John asked.

"Yes, I just brought it back from a complete checkout. Everything seems to be fine, but it wouldn't work on a beam we bounced off the Orbiting Base last night."

"Maybe your bandpass was too narrow," John said, helping her with her load.

"I checked . . ." Fred tried to say.

"Or maybe you were getting a frequency shift."

"That could . . ." Fred tried again.

"Oh, do you think so?" Jeanne asked wide-eyed. "I just don't know much about these things," the winner of the local science fair for the last three years said innocently.

"Maybe we can try it on the ridge outside of town tonight . . ." were the last words Fred heard as they disappeared out the door.

He chuckled. "Bubble memories, laser mirrors, and electric cars, but some things never change!" ■

Try A Micro Contest Logger

-- the 6800 does it all

Gary E. Belcher KH6GMP
91-962 Akaholo St.
Ewa Beach HI 96706

Any contester will tell you that the removal of duplicate contacts from a contest log is absolutely necessary but can be an arduous and time-consuming chore, particularly when a large number of contacts are involved. For example, say 2000 QSOs are made on one band. Each callsign must be compared against all other callsigns on that log, in order to determine if a duplicate exists. When done manually, with pencil and paper, this operation can take nearly as long as the actual on-the-air operation, and, needless to say, it's nowhere near the fun.

Naturally, since I do operate in all the major contests, the first function I wanted to perform with my new micro, once it was up and running, was the removal of duplicate contacts from a contest log. The program presented here does just that. It reduces the operation to merely entering each callsign from the log into the processor via the control keyboard. Duplicate contacts are identified with both an audible and a visual indication.

The ultimate contest program, of course, would be used during the actual operation of the contest and would identify duplicates before they were logged. It would maintain the log for you, printing it out on hard copy for submission to the sponsor. Such a program would be beyond the memory capacity of my system, and I have no hard copy device. I, therefore, designed this program to be used after the contest. Callsigns are taken from the completed logsheets, and the duplicate contacts identified must be marked on the logsheets as such.

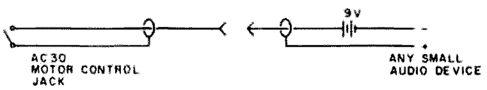

Fig. 1.

This program is written for the SWTPC 6800, with the CT-1024 control terminal and AC-30 cassette interface. The AC-30 is necessary only in the generation of the audible alarm described below. As suggested by SWTPC, memory locations 0000 through 0020 are unused. The program requires $478_{(10)}$ bytes of memory, leaving all remaining memory for the workspace. Each callsign is assigned six bytes, plus one for the end-of-callsign control character (a period).

It is possible to process 1100 callsigns in 8K of memory, while 500 may be handled by 4K. As you will notice in the assembly listing, maximum use is made of the INEEE and OUTEEE routines contained in the Motorola Mikbug firmware, and direct addressing is used extensively.

Upon execution of the program from its starting point, location 002F, the home-up and erase to end of file functions are performed to produce a clean screen, and then the "Enter Callsigns" screen message appears on the control monitor. Callsigns of variable length are entered from the keyboard, each followed by a period. They appear on the monitor in column format at the left margin. In the event of a typing error, a slant bar is entered (anytime before the period) and the erroneous callsign may be entered correctly. A line feed, carriage return, and erase to end of file string follow each callsign entered, to produce the column format and to cause a clean screen on page changes. The compare routine is bypassed for the first callsign entered. After that, as each callsign is entered, it is compared to all others already in the workspace. Upon detection of a duplicate entry, the screen message "Duplicate – Type A Space" appears following the callsign, and the audible alarm alerts the operator. The alarm is extinguished when the space (actually any character will do) is typed.

This audible alarm feature was included only as a convenience, so if your system does not include the AC-30, don't worry; the program will still function as written. You will, however, have to glance

up at the screen after each entry to check for the visual indication of a duplicate on the monitor screen. Any audio device may be used for the audible alarm. Simply place the auto/manual switch of the AC-30 in the auto position, engage input A as a reader, and use the motor control jack A as a switch to turn on the audio device. (See Fig. 1.) The "Duplicate" and "Memory Full" screen message strings contain reader-on commands, and a reader-off is generated after keyboard input. I merely plug in a cassette recorder locked in the play mode and containing a program tape. Crude as it may be, the Kansas City Standard tones never fail to get my attention when the recorder is activated by the remote switch.

After the last callsign to be processed, key in a dollar sign, which terminates the entry and compare function and begins a "Print" function. Should the end of your memory be reached before you have come to the last callsign, the "Memory Full" screen message is displayed along with the audible alarm. The dollar sign must then be entered to begin the "Print" function.

The "Print" function actually serves no purpose, except to allow a simple recheck to insure all duplicates have been properly marked on the log. The callsigns are displayed at the left margin in column format. Printing continues rapidly until an identified duplicate contact is reached. The callsign is followed by a "Duplicate" screen message, and you are instructed to type a space to continue. After the last callsign is displayed, a screen message instructs that you type a "P" to print again or a "C" to clear. If the "P" is selected, the print operation cycles through again, while a "C" clears the memory workspace and prepares for the entry of a new series of callsigns, perhaps the processing of another band.

Included in the program are two constants, which are dependent on the memory capacity of your system. Location 0023 contains the highest memory address, while 007F contains the address of the highest callsign starting point in memory. I have used 1FFF and 1FF9, respectively, for an 8K memory. If you are using 4K, simply change to OFFF and OFF3.

This program should prove to be a most valuable addition to your program library. You can process your log in a minimum of time and still have complete confidence that you are submitting a clean log. ■

Fig. 1. Program listing for GLOBAL.

How many of you DXers now keep a hand calculator next to your rig? After Frank Kelly described "Global Calculations for the DXer" in the August, 1976, issue of *73 Magazine*, no doubt some of you have tried it. The article showed how to calculate the distance between two places anywhere in the world.

When you're working that rare DX in Timbuktu, it's always nice to drop a tidbit of information like, "I calculate that our QSO spans a distance of 8346 kilometers, QSL?" Pretty impressive-sounding information, no doubt, and it's a novel topic for conversation.

After a while, though, you can become tired of doing all of that number-crunching every time. No doubt some of you have let the bit bug bite. Either you have picked up some type of microcomputer or are at least interested in them. If so, let the number-crunching bother you no more. Let the computer do it!

This article describes a computer program that calculates the shortest distance between any two points on the globe. All you need to do is type in the latitude and longitude of any two locations on Earth, and it prints out the distance in miles and kilometers.

I call the program GLOBAL, for obvious reasons, and it is written in the programming language BASIC. GLOBAL is listed in Fig. 1. It is very straightforward and takes very little time to run. In Fig. 1, statement numbers 40 through 90 have the computer ask you to input information about your location or the location of the first station. (If you are holding a three-way QSO, you could tell the other fellows how far apart they are.) Statements 100 through 180 calculate the parameters for the first station. Unlike Kelly's method, your station can be located anywhere in the world. So, if you're not in North America, you can still use the program. Statements 200 through 250 ask you questions about the second station's location, and statements 280 through 370 calculate the parameters for his location. The actual calculation of distance is carried out from statement 390 through 410, and then the distance is output in both miles and kilometers.

The language BASIC that I used may be slightly different from the one that you're using, but I've attempted to make it so that the program will work on most machines. Notice that when inputting latitude, you must type 1 for north or 0 — zero for south latitudes. If your machine will accept what they call string variables (mine won't), then you could change the program to accept the letters "N" or "S", or the words "North" or "South." The same applies for longitude. You will need to alter the IF statements: 150, 170, 300, and 360. For instance, 150 would become: 150 IF Z$="W" then 170. Also, all of the variables, A, B, Y, and Z, would need to be changed to A$, B$, Y$, and Z$, since these usually denote string variables.

One other important point

```
RUN
THIS IS GLOBAL

MY LOCATION IS
LATITUDE(DEG,MIN, 1 FOR NORTH-0 FOR SOUTH)
?40,52,1
LONGITUDE(DEG,MIN, 1 FOR EAST-0 FOR WEST)
?73,19,0

HIS LOCATION IS
LATITUDE(DEG,MIN, 1 FOR NORTH-0 FOR SOUTH)
?48.52,0,1
LONGITUDE(DEG,MIN,1 FOR EAST-0 FOR WEST)
?2.2,0,1

DISTANCE IN MILES                3596.772218
DISTANCE IN KILOMETRES           5788.28553
```

```
RUN
THIS IS GLOBAL

LATITUDE(DEG,MIN, 1 FOR NORTH-0 FOR SOUTH)
?40,52,1
LONGITUDE(DEG,MIN, 1 FOR EAST-0 FOR WEST)
?73,19,0

HIS LOCATION IS
LATITUDE(DEG,MIN 1 FOR NORTH-0 FOR SOUTH)
?22.54,0,0
LONGITUDE(DEG,MIN, 1 FOR EAST-0 FOR WEST)
?43.15,0,0

DISTANCE IN MILES                4793.847786
DISTANCE IN KILOMETRES           7714.739241
```

Fig. 2. Two runs for GLOBAL. The first calculates the distance between Huntington, Long Island, NY and Paris, France. The second calculates the distance between Huntington and Rio de Janeiro, Brazil.

is that GLOBAL converts degrees to radians before calculating. Make sure that your version of BASIC uses radians for angle calculations. If your BASIC needs degrees, then you'll have to eliminate the conversion factors (3.14159/180) from statements 110, 120, 280, 290, and 410, and you'll have to change pi (3.14159) to the value 180 in statements 340, 350, and 400. One last thing you should know is that part of statement number 400 reads like this: SQR(1-A1↑2). The A1↑2 means A1 to the exponent 2, or A1 squared. Some machines may need that written A1**2, or, if all else fails, just multiply A1 by itself (A1*A1). So with these hints in mind, you should be able to get GLOBAL to perform for you, no matter what kind of BASIC your machine eats.

Fig. 2 shows the output for two different runs of the program. These two runs are identical with the examples that Frank Kelly gave in his article. The first run calculates the distance between Huntington, Long Island, NY (40°52'N., 73°19'W.) and Paris, France (48.52°N. 2.2°E.) as a total of 3596 miles, which is the same as Kelly's figure. The second run calculates the distance between Huntington and Rio de Janeiro, Brazil (22.54°S., 43.15°W.) as 4794 miles, again the same as in Kelly's calculations.

If you get tired of typing in your own location, you can always calculate L1, L2, K1, and K2 from your location and assign these in the first statements of your program. You could then eliminate statements 40 through 180. By the way, GLOBAL takes up very little space in memory, less than 1K, and the above measure would reduce it even more. ■

Micro Meets JANET

-- meteor scatter, anyone?

The idea of utilizing meteor scatter propagation for data transfer first occurred to W5HK and WB9WXM during one of their long, frequent bull sessions on FM this past April. Bob had just received his first computer, an 8080, and Steve was nearly through reading *Hobby Computers Are Here.* Both were looking for a way to genuinely show the computer's value in VHF communications. It was not long before the pulse data characteristics of data transfer encouraged them to look at an old mode that has been almost forgotten — meteor scatter. This mode has never been highly popular, either commercially or with the amateur, because it requires either high speed CW or a very quick mouth on SSB to communicate. Information transfer is tedious and requires more patience than most of us have. But wouldn't this mode be ideal for the microprocessor and the transfer of data in quick bursts?

A look through a nearby technical library showed an interesting fact: Most information on meteor scatter was written in the 1950s, and there appeared to be considerable interest in it until satellites attracted the interest and backing of government and industry. Almost an entire issue of the *Proceedings of the IRE* was devoted to the mode in late 1957. In it were described the successful commercial experiments conducted between 1953 and 1956 using meteor scatter. The JANET principle refers to the technique first suggested in 1950 by McKinley and proven commercially in a long term RTTY link over a 950 km path in Canada between 1954 and 1956. JANET utilizes a duplex system of two stations and a continuously transmitting carrier. When A is transmitting, B is listening for the signal to appear from a trail. These ionization trails appear in the upper atmosphere and vary in length from 15 to 40 km. They have a thickness on the order of 1 meter.[1] When the detector registers a predetermined signal level, it will begin storing data. JANET, as the IRE article states, was named after Janus, the Roman god of the doorway who looked both ways at once.[2]

Meteor scatter itself is a result of the continuous, although sporadic, bombardment of the Earth by meteorites. Approximately 10^{10} particles, representing a mass of approximately 1 ton, hit the Earth each day.[3] The important point is that a fiery spectacle is not required to produce a usable trail; grains of sand that are invisible when entering will suffice. The meteoric particles enter the ionosphere at a height of 80-120 km. "Although a single observer may see only two or three visible meteors per hour, hundreds of trails can be detected in the same period by sensitive radio equipment."[4]

The average number of trails varies from season to season, for reasons best left to further reading, and meteor showers can greatly enhance the duty cycle of communications. For purposes of reliable year-round communications, we are interested in the fact that trails are always present and that their occurrence is always frequent enough to ensure a reasonable information rate (60 wpm at a continuous RTTY speed of 1300 wpm, for example, in tests conducted in the 1950s).

The characteristics of the trails are such that fading is a problem because high altitude winds can shift the ionized gas trail slightly; trails that are either underdense or overdense can introduce distortion of the signal. A small number of trails appearing at the optimum angle between two points become the vehicle for the communications link. An effective system would endeavor to use a single trail at a time in order to minimize fading and multipath distortion. Thus, the practical duty cycle would be decreased, to less than .05.[5] Because of the critical angle of entry for meteors to form usable trails between points A and B, the optimum path is not a great circle route, but, rather, a few degrees to either side. An effective antenna for 50 MHz would be a non-highly directional yagi. Great success was achieved with JANET, using two five-element yagis aimed 8° either side of the great circle path and 8° above the horizon. Because of the Earth's rotation, more trails will appear on one side of the direct path in the morning and the other in the evening. This antenna permits both propagation paths to be utilized.

At the time the JANET principle was published and advocated as a commercial viability, the error rate had been reduced to less than 0.1 percent, and average information rates from 30 to 60 wpm were achieved. The major

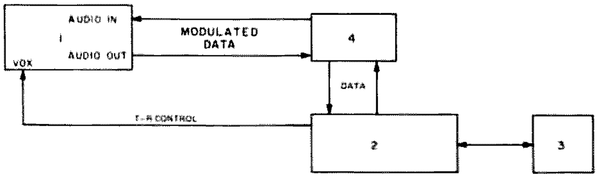

Fig. 1.

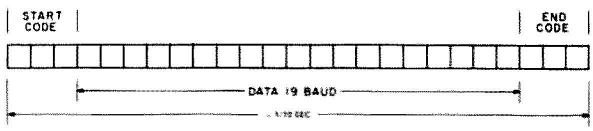

Fig. 2.

problem, as was to be expected, was to develop effective gating equipment to determine when the signal from the distant station was at a usable threshold.

Since most of the work on the meteor scatter mode has been done in the 30-50 MHz range, it is difficult to predict exactly what the relative values for error rate and duty cycle would be on 144 MHz. From discussions with other amateurs, we learned that meteor scatter commonly provides 3-6 second trails on six meters, 1-2 second trails on two meters, and possible occasional trails on 432 MHz. From our attempts to find articles and to locate other individuals who were familiar with the mode, we learned several things that were disappointing. Very little was done with the mode commercially after the satellite became a reality, very few VHF amateurs had ever worked the mode or knew anything of it, and a great deal remained to be done at 144 MHz and above to determine its characteristics.

From our investigation of the mode, we became convinced that meteor trail scatter, although practically forgotten, had very considerable potential for data transfer and that experimentation on two meters would be essential to find the answers. In summing up the mode's disadvantages (from a data viewpoint), there are few. The path appears to be limited to 2000 km, is not as fast as satellite or other continuous modes, and would require well-aimed antennas and precision tuning between amateur stations to effectively utilize the short burst time with a minimum of "search and setup" time. These disadvantages are *vastly* overshadowed by the advantages:

1. Reliable communications, regardless of sunspot or solar conditions;
2. 24 hour a day usability, unlike the amateur satellites;
3. A reasonably low error rate, due to the inherently stable condition of the path for the short time it is there;
4. A degree of security and privacy not achievable on HF or satellite repeaters — the critical angle of usable trails between points A and B precludes usable signals being detected beyond several hundred kilometers around each station;
5. Spectrum efficiency and reuse as a result of 4 above — indeed, the authors of the 1957 article on JANET believe stations could operate on the same frequency if they are operating from moderately right angles to one another's paths;
6. Above all, this mode is uniquely suited to the sporadic, parcel nature of data communications; the birth of hobby computers makes meteor trails viable as they never have been before, making possible an inexpensive and reliable way for nationwide contacts using the home computer.

At this point, we decided to develop a working system built around the 8080 uP. First, we had to decide what basic system configuration could best utilize the meteor burst mode in a relatively economical fashion.

Meteor Burst Modes

Several possibilities exist for the automatic transfer of data via meteor burst. In decreasing order of complexity:

1. Full duplex — A duplication of the JANET system provides a station with the ability to utilize the greatest number of trails, thus increasing usable transmission rates. For the exchange of large amounts of data, it is probably the only viable technique. For the amateur, it has several pitfalls. The narrow spacing that would have to be used on two meters (if the repeater segment were to be avoided) would require an expensive duplexer and cavities. Critical retuning would have to be performed every time the frequency was changed. A much simpler duplex system, available to any amateur, would involve crossband operation between 2 and 1¼ meters or 2 and 6 meters. This alternative should be considered in the future.
2. Modified full duplex — In theory, a commercial base station, amateur repeater, or television station could be monitored by a distant meteor burst station. The reception of the monitored signal from point A at point B could be used to gate the amateur transmitter to release data. If both points A and B utilized this gating method, higher transmission rates could be achieved.
3. Simplex — This requires selection of defined transmission periods that are long enough to have a high probability of hitting one usable trail. Much less information could be exchanged than with 1 or 2, but for the VHF amateur using a 300 baud per second rate with a microprocessor, 30 baud, or approximately six words, could be transferred in a 1/10 second burst. This is more than adequate for DXing or short messages. It is the suggested technique because of its relative cost. One minute transmissions would result in a high probability of completed QSOs in less than ten minutes, with none of the tedium associated with conventional meteor burst operation. Experimentation would determine the best transmission length and data parcel size. After this technique was developed, transmission bursts might effectively be decreased to rapidly transfer data. Of course, an individual interested in high volume traffic would then find considerable merit for constructing a station based on duplex or crossband operation. For most amateur operation, simplex operation would be fully adequate. It is this system we are developing and to which we are encouraging interest be directed.

Simplex Version

Having determined that we would utilize a simplex system, we decided that we would need the following basic components:

1. 2 meter FM transceiver with 100 Watts and 4-7 element yagi;
2. Microcomputer;
3. TTY or video terminal;
4. Modulator and demodulator.

A block diagram using the simplex version is shown in Fig. 1. The data format is shown in Fig. 2.

Station A Send	/ / /PLS (S) QSL (S) TNX (S) 4 (S) QSO (R) +++
Station B Receive	PLS QSL TNX 4 QSO
Station B Send	/ / /73 (S) BOB (S) OK (S) QSL (R) +++
Station A Receive	73 BOB OK QSL
Station A Send	/ / /73 (S) WB9WXM (S) QRX (R) +++
Station B Receive	73 WB9WXM QRX
Station B Send	/ / /W5HK (S) QRX (R) +++

This is how a typical QSO might appear. Total QSO time — 8 minutes. A new state was worked on two meters, direct and with meteor burst data transmission. (S) = space, (R) = return, / / / = start code, and +++ = end code.

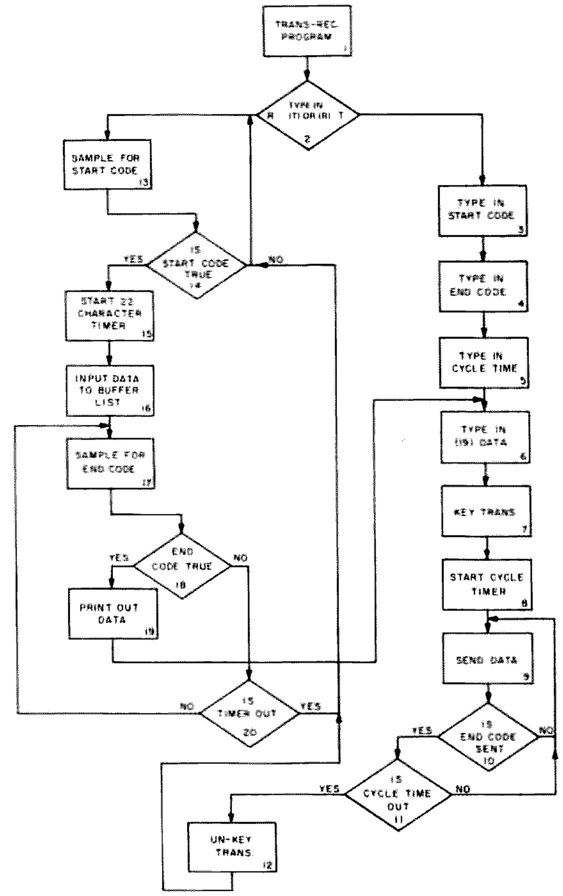

Fig. 3. Flowchart of the program that will be used in the first system.

1. Initial program waits for a command.
2. Decision block: If a (T) is typed in or an (R), will either jump to block #3 or #12.
3. Start Code block: Type in the Start Code to be sent and to be sampled when in the receive program.
4. End Code block: Type in the End Code to be sent and to be sampled when in the receive program.
5. Type in the cycle time desired; ½, 1, 2 min. etc. This is the total time the data message will be cycled.
6. Type in the message to be sent, up to 19 characters. The last character of the message has to be a carriage return.
7. Because of carriage return being typed, the system keys the transmitter.
8. The cycle timer is activated (this is a software timer).
9. The total data is sent – Start Code, message data, End Code.
10. Decision block detects if the End Code is sent, if (no) is generated the program loops back to #9 until a yes is generated in #10. Once this happens the program jumps to #11.
11. Decision block to determine if the cycle time is reset: If (no) the system continues to send the data until the cycle timer is reset. Once this is true, the program jumps to the receive block #12.
12. Un-keys transmitter for receive portion of program.
13. Sample for Start Code.
14. Decision: If Start Code is false, then continues sampling. If true, jumps to #15.
15. Start a timer whose length is equal to the maximum number of remaining characters, which is 22.
16. Load data to buffer register.
17. Sample data for End Code.
18. Decision block for End Code: If true, go to #19, if false, go to #20.
19. If End Code was detected, then the data between Start Code and End Code is printed out.
20. If End Code was not detected, this decision block is used to determine if the 22 character timer #15 has timed out. If no, jump back to #17. If yes, return to #13. Begin Start Code sampling.

Fig. 4.

Mode of transmission will be narrow band FM with deviation between 2.5 and 5 kHz. Experimentation will begin at 5 kHz. The modulator and demodulator are based on the Audio Cassette Standard described in the article entitled "A Nifty Cassette-Computer System" in *Hobby Computers Are Here.* Since this standard has been adopted by the industry for the audio transfer of digital information, it provides the most economical and effective means of transferring data, at the reasonably fast rate of 300 baud per second.* Secondly, although the original JANET system utilized double sideband AM with audio frequency shift keying, narrow band FM provides advantages in terms of signal to noise ratio and noncriticalness of tuning. Those who have operated FSK on HF will appreciate the criticalness of exact tuning. FSK is not tolerable with a short burst meteor mode. With FM, a signal tuned in reasonably close will provide a usable signal, and, unlike FSK, the frequency of the audio tone is automatically in tune. As a further bonus, this provides the multitude of VHF FMers with the ability to use existing FM gear, if they couple it with an inexpensive microprocessor-based data system. Of course, further experiments can use SSB, FSK, or other more exotic modes, such as decimal frequency shift keying. The goal here is to provide the largest number of amateurs with an inexpensive yet effective way of using this mode.

Now let's return to the data format and give it a closer look. Total transmission was chosen to be 25 baud in 1/10th of a second or less, repeated for 1 minute. The repetition is to insure that a complete data transmission will be received. The first 3 baud are the recognition code, thus allowing the receiving station to know if a transmission is starting. The next 19 baud are information such as call, QTH, handle, etc. Last, the remaining 3 baud are the ending code to tell the receiving microprocessor that the message is completed. Total transmission time is ≤ 1/10th second; repeating for 1 minute will cycle this 600 times. Only experimentation will determine if this time is sufficient. When the receiving station has decoded an ending code, it will print out the message, and the receiving station can then send a reply by the same format. When sending data, the microprocessor will key the transmitter by using the VOX circuit; this will enable the transceiver to be either receiving or transmitting as determined by the microprocessor program.

That's the total system in operation, but one of the most important things is the microprocessor program. Since both W5HK/9 and WB9WXM are not the most proficient programmers of microprocessors (we are both learning), we brought in a third party to write the program. (See Figs. 3 and 4.) Gary Chaffin is a non-amateur who has a great love for the microprocessor and programming; he is also one of the sharpest people we know in that field. The microcomputer we are using is the IASIS Computer in a Book. Besides being a learning tool, it is also a powerful microcomputer using the 8080A.

Conclusion

At this point in time, we are actively constructing a system based on the principles described in this

*In this article, the tones of 2400 cycles for mark and 1200 cycles for space are suggested. These tones are relatively inexpensive to generate; a stable 4800 Hz can be divided by 2 for mark, and divided by 4 for space.

article. The reason for writing this article now, rather than after a system is fully operational, is quite simple; we need the assistance of other interested VHFers outside of this area to prove the system. Whereas an EME enthusiast can test his system by listening for his echo, the narrow propagation angles and short time for reflection from a meteor trail only 100 km in altitude make it impossible to use the same technique.

We believe this technique has considerable potential and feel it is an effective marriage of the microcomputer and the meteor burst mode. It has the potential for contacts that are not limited in duration as are present OSCAR QSOs, or distance as is the case with conventional VHF propagation. From the Chicago area we should be able to work most of the country on meteor burst. We welcome those with computers and interest to join us on 145.180 this winter. We could all be pleasantly surprised with what can be done when JANET is refurbished and utilized in an environment where she best functions — the short data bursts of the modern microprocessor. ■

Run, Sheila, Run!

-- real-life radio control

The fifteen-year-old girl was placed in the starting blocks. A silence fell over the stadium. Everyone was tense, straining. The starter raised his pistol and called, "Runners on your mark, ready!"

"BANG!" The report of the starter's pistol pierced the silence and tenseness of the stadium. Sheila leaped from the blocks like a coiled spring, and, for the next 14.2 seconds, the only sound to be heard was the pounding of her feet on the cinder track, along with the almost-monotone of my voice speaking into a microphone telling the blind Sheila, "Left – left – right – looking real good – half way – now, you're there – real good – that's all, you're done now."

Coach Jim Blasingame aims Sheila Holzworth in the starting blocks.

I laid the microphone down and turned the transmitter off, as there was no longer any need for it. Her teammates had met her and were now walking her back to the stands. Sheila was very dejected with her time. The 14.2 was not very good for the one-hundred-yard dash. She had been very nervous on this run, as she had gotten into the fence on an earlier practice run that day. She had had only about a dozen practice sessions with the radio equipment she was using.

14.2 seconds for the one-hundred-yard dash may not be a good time for your average runner, but Sheila changed that the following week with a 13.2 time. The second time she was not as nervous and had had a few more practice sessions. Sheila is now within three-tenths of a second of the rest of her team, which is not bad for a girl who, only five years ago, lost both of her eyes. It was a freak accident in which the orthodontic headgear she was wearing broke and flew into her eyes. Her father, being a doctor, had given her immediate first aid, and she started to recover. But a secondary infection set in, and it became necessary to remove both of her eyes.

Now, five years later, she wants to do, and does do, everything that other fifteen-year-old girls do – skateboarding, roller skating, riding horses, bicycling (tandem) – and she planned to participate in the bicycle ride across Iowa this year. She also begs to be allowed to drive a car. Prior to the accident, she was very active in track and athletics, but the accident slowed her down a bit. She used to run with her coach in front of her, but in the high school meets this can't be done.

A friend of mine, who also knows Sheila's family, asked me one day, "Ed, you're a ham and know about radio; is there any way that we can

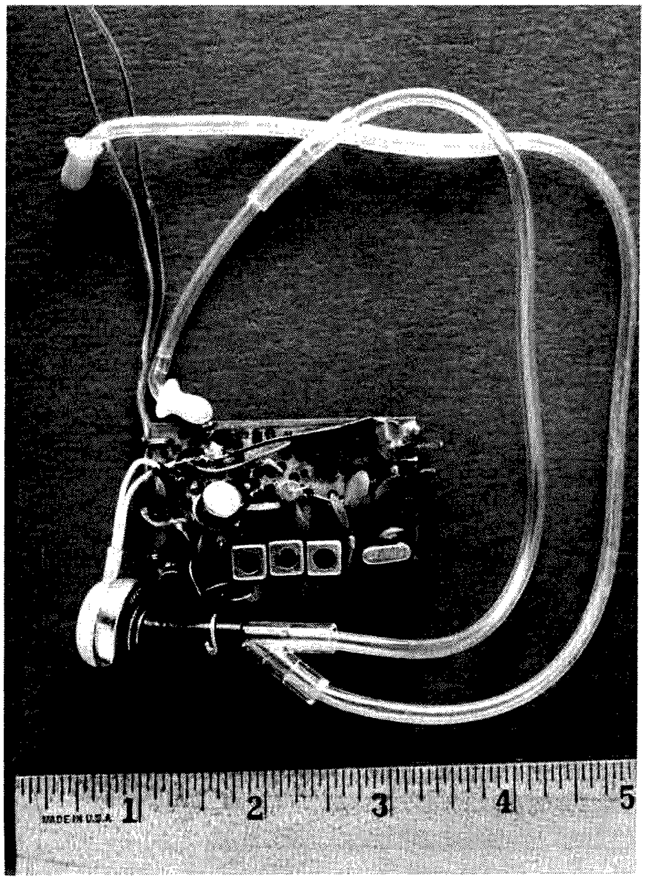
wire Sheila for sound, so she could run in track?"

My response was, "Let me see what I can scrounge up and what is available." I was thinking of two meters and a pocket scanner, on a little used frequency, with earphones. It sounded like a good idea, if a bit bulky. But, at least, it could be made to work, and this kid really wanted to compete with the other kids on their level.

A quick call to another ham, Ron Kinton WBØMBZ (who knows a lot more about radio than I and has a bigger junk box), revealed that it might take time to get crystals for an odd frequency and that the plain bulk of the pocket scanner might not be good. He said he would get back to me the next day. Sure enough, he did, with a model airplane receiver donated by another ham, Tom Taylor KØHHE. It was already on six meters, so Ron proceeded to modify it by removing all the heavy digital circuits and adding one stage of audio amplification. This proved to be sufficient to drive a high impedance earphone. To get the receiver down to the lower part of six meters, a surplus crystal from an old Collins aircraft transmitter was found. These components combined to give us the magic number of 50.4 MHz for a receiver frequency.

Ron gave me the receiver and told me to tune it up and make it work. He even donated his ancient Gonset Communicator III for the cause. But he didn't have a 50.4 rock. His vfo for the Gonset didn't work either. I had a Heath sixer and a 50.4 rock, which I soon found out was no good either. But the Heath HW-16 I used for a CW station had a vfo that worked on six meters. It was pressed into service to provide the proper signal to tune the receiver with. The HW-16 and vfo combined with a counter enabled me to tune the receiver down to the proper frequency, and, in the meantime, I was able to locate another 50.4 crystal. After a few hours of tweaking i-fs and coils, it became apparent that I needed to get further away from the transmitter. I then called yet another ham, Ken Freberg WBØIFE. Good old Ken, he never questions the crazy stuff I do, just helps out any way he can. We took the Novice course together and got consecutive calls, and I have had him over for several projects. Ken took over the duties of operator, and I became a "Sheila" and proceeded to walk up and down the street at night, in a light rain, muttering to myself, while trying to fine tune that tiny receiver, which we now had down to just about one ounce of weight, including the earphone.

After satisfying myself that this just might work, I contacted Sheila's family, and we made arrangements for a few tests. This proved to be very encouraging. I presented to Sheila the tiny receiver and the large, seven ounce carbon battery that we had for practice. Now was the time for the first of many trips for Sheila, with my voice in her ear. She held the receiver and battery in her hand, while holding the earphone in her ear – it wouldn't stay in her ear, so she had to hold it. A walk down her long, broad driveway was an outstanding success for both of us. I was even able to guide her up to and around several parked



Receiver module showing the high impedance earphone with medical IV tubing and Y junction. The splice between the IV tubing and the Plantronics earphones is medical catheter tubing.

Sheila with her headband. The object on this side is a nicad battery. One antenna is worn in front, the other in back, both under her shirt.

cars. It is difficult to say who was more excited over the promises this held for Sheila, but it was decided right away that she should try to run with the radio. A belt was brought out to tape the heavy battery to. Some surgical tape was used to hold the earphone in place and also to wrap the receiver with, so it could be pinned to her shirt. Her coach, who lived nearby, showed up, and we proceeded to let Sheila run. In her very own tunnel, in the absolutely black abyss world of the blind, with only the voice of the person who held the microphone to guide her, she ran.

Her best friend, Kim Novak, was asked to try as a controller for her. Because of their long friendship, we thought she would be good, but Kim got too excited and was unable to tell Sheila what she had to know. Her coach then took over the microphone for the rest of the test that day. It soon became apparent that we had a real winner on our hands. This girl and her abilities are fantastic.

I returned to my home and proceeded to rework all the external hookups, so the receiver could be placed in a sweatband. My wife made a pocket in the headband for the receiver. Another pocket was added later for a nicad battery, which was added for the competition runs. The placement of 2 antennas was necessary, as her body would null the signal when she was between the transmitter and receiving antennas. With the system pretty well completed and refined, I met with Sheila nearly every day for practice. Because of our practice schedule, I have become Sheila's controller. True, it takes time, but what better way to develop a hobby into something positive?

This girl was so eager and trying so hard that she developed shin splints, which were extremely painful, but she kept on trying. We finally had to quit for a few days, so Sheila could recover. I found that if I asked her if she hurt, the answer was always "no," but if I watched her very closely, I could tell when she hurt. I had to watch her constantly, until she finally realized that she couldn't perform when her legs were sore.

It is still a real problem to keep her in the narrow space that is allowed on a track, but I am sure that the day will come when Sheila will keep in her lane, and she will come out in one of the first three places. The amazing thing is the faith and trust this girl has to run down a track with no more than someone telling her which way to go! We have all tried it at one time or another, and the results of seeing another ham walking down the track blindfolded, with the radio for a guide, can sometimes be quite funny. When Sheila does it, running faster than any of us old men can, it is nothing short of amazing. She makes mistakes, but don't we all? They don't make her feel very good, but, with practice, I am sure that she can do the things that she wants. I don't think I can ever take this girl and her efforts as commonplace or for granted. I constantly marvel at her abilities, and I will be forever grateful for the opportunity I have had to work so closely with her. The fact that amateur radio has had a hand in this project just makes my hobby that much better. ■

Ron Kinton WB0MBZ making some adjustments on the Gonset Communicator III during a practice session, with Sheila standing next to him. The antenna is a 5/8 wave on 2m extended to ¼ plane on 6m using aluminum foil for a ground plane. Works FB, 1:1 swr.

CB to 10

-- part VI: antenna suggestions

Tom M. Murphy K5UKH
Rt. 1, Box 301A
Ethel MS 39067

One of the better things to happen to amateur radio lately is the availability of lots and lots of low cost communications equipment – new and used Citizen's Band transceivers. These range from old tube types to modern solid state units.

Want to be cheap? Just do as I did – find an old tube radio, get it into operating shape, and convert it to 10 meters. I was given a Johnson Messenger 1 tube radio by a "good buddy" who was all hung up on his latest 40-channel play-pretty. Well, sort of "given" . . . it cost me three beers and a quick radio repair job. A couple of tubes later (which I scrounged), I had it going great on CB channel 11. The radio was putting out 10 Watts AM into a wattmeter and dummy load.

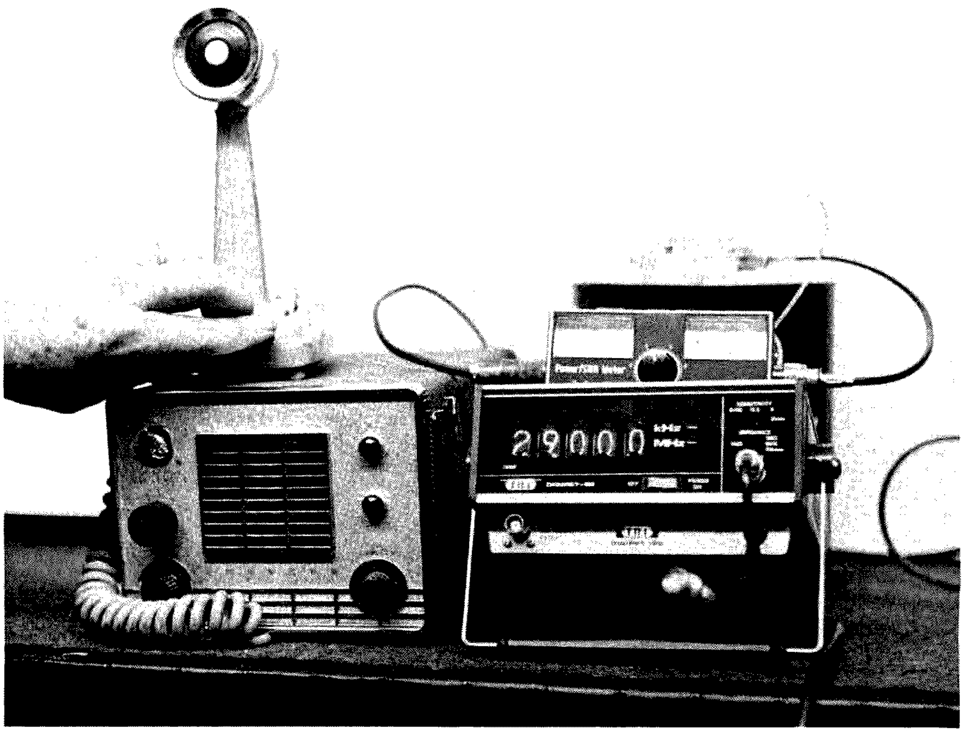
Photos by James Clegg

That's one of the reasons most of the tube types were (and still are) so popular. They could be "tweaked" for more output very easily. In this area, 29.000 MHz is coming into use for channel 1, since there is really no established band plan for this equipment. Let the CW boys use 28 to 28.5, of course; SSB has 28.5 to 29; and let the AM activity start at 29.000 through 29.290. That gives everyone a lot of room.

The 2 meter band is getting more and more crowded. Onward and upward is the cry, but the cry I hear right now is my pocketbook. So, let's fall back and regroup and have a whole bunch of fun in the process. The Johnson has a 5-channel capacity, a built-in ac power supply, and puts out 10 Watts with no problems. The conversion was about as simple as sticking a couple of crystals in. You just have to tweak on the rf stages, both receive and transmit, for optimum performance at 29 instead of 27 MHz.

Checking with a number of good buddies in the area reveals a huge quantity of tube type radios. These are just ideal for conversion to 10 meters. I have a solid state rig converted to 10 in my truck, and it works like a champ. Having solid state for mobile and a cheap tube set for base use is the way to go. The people I want to talk to can now get me on 10 meters instead of 2. Because it's sparsely populated, there's no problem like on 2. It was hard to work SSB on HF without the 2 meter radio sounding off. So, this way, if DX is around, I can get a call or give one to alert the "good guys."

What about antennas? Well, there is a lot of "scrap"



10 Watts at 29.000 MHz.

lying around. This scrap is good stuff, and it can usually be obtained for the asking. I've seen many antennas whose only problems were that the fellows using them couldn't make them work, shorted PL-259, cut coax too short, etc. The latter may be just fine for this use because that's what you have to do to go up in frequency, of course – generally cut off about 2 inches for 29 MHz.

The antennas for mobile use are of many types, ranging from cheapos to the expensive, high quality items. With base-loaded coils, I just snip a couple of inches off the whip, rather than worrying about getting into the coil. Then there are the center-loaded types; again, take a couple inches off. On my truck I use a 4-foot, fiberglass, top-loaded antenna (Radio Shack, new $9.95 with $4.95 mirror mount), which I got for no cost when one of the fellows was getting the swr down and trimmed it off too short. It started going up on him, and that was it; he had to scrap it and get a new antenna. That was fine with me; it's going in my direction anyhow. There's a rubber tip over the end; remove it, and you will see the end of a wire. Carefully take your pocketknife, fish the wire out, and trim. Of course, all the trimming is done while using the 10 meter radio in conjunction with an swr meter.

Then there's the full length "whip," 102 inches long, plus a 4-inch spring and ball mount. If you like it "whipping" around, trim a couple and get talking. As you go down the street, you will come to know the height of tree branches above the street.

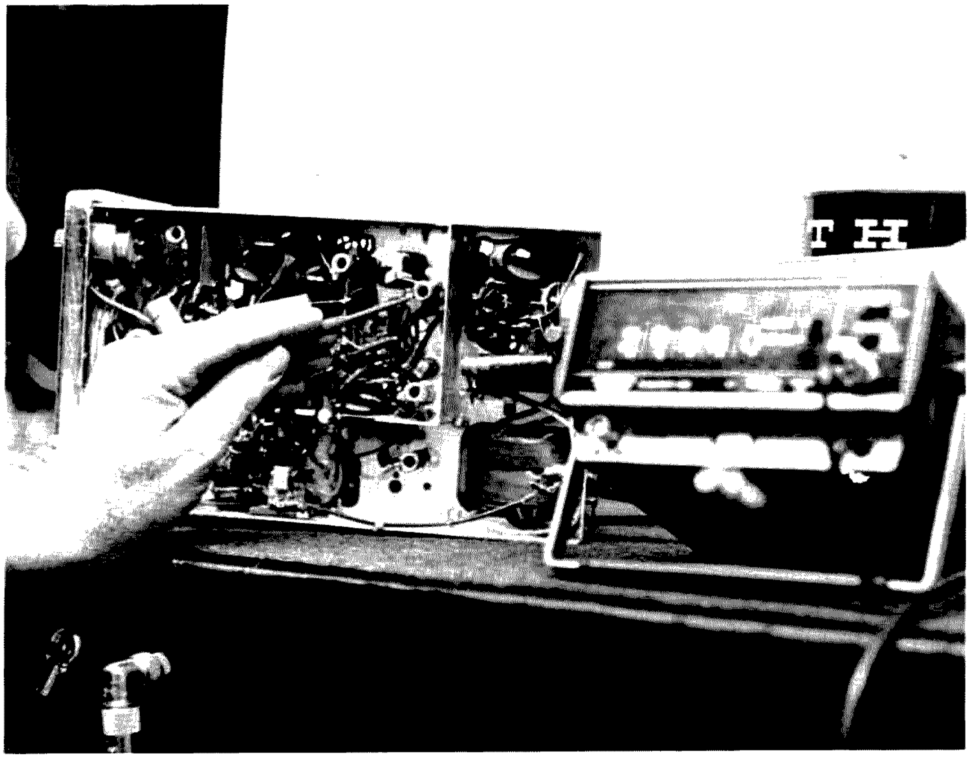
Seriously, there's a world of CB antennas out there just for the seeking, so put the old ham spirit to work and scrounge! Base station antennas are equally as easy to convert. Just a little trimming is all it takes. They range from the cheapies that have no gain (actually a loss compared to dipole reference), to quarter wave, to the big, long ones, more than 19 feet, that have several dB of gain. Again, I have a preference as to type. I just don't like the big, long ones; they're hard to handle and sure do catch the wind. However, if it's cheap, the price is sure hard to beat, so that could be the way to go. I use a compact antenna called the "Starduster." I believe it sells new for about $45.00. I spent a couple of hours helping with an antenna erection and inquired, "What are you going to do with that old antenna?" I got it free or, at least, as a reward for my help.

The advantage of a compact antenna is that it can be easily mounted on top of the HF or whatever beam without a lot of trouble, whereas the long ones would be just about impossible. Of course, the trimming takes place closer to the ground. I just put the antenna on a 20-foot mast to make adjustments, and it changes very little when I finally put it way up there.

Beam antennas? Well, there are uses, of course. Say there's one specific direction you want; you could convert and side mount the beam. The average CB beams are just too big and unwieldy to be practical for our use, unless they're on top of a tower, and the chances are you already have a good HF beam. I have a TH-6DXX, and 4 working elements on 10 meters, which are enough for me. If it is difficult to make contact on the vertical polarized ground plane, then we just switch to horizontal on the existing HF beam. Also, the ground plane works very well in the omnidirectional pattern, to catch calls from mobiles that may be in any direction, and, of course, band openings. With the ground plane, I can hear stations that I would otherwise miss if I was using the beam and did not have it turned in their direction. The ground plane is up 85 feet, and the distances worked are amazing – base to base, and base to mobile. If I want to talk to my good buddy 60 miles away, I just ring his number (channel 1, 29.000 MHz), and away we go.

There are all sorts of goodies to be found. I honestly believe that those fellows must buy PL-259s by the bushel. Just scrounge, and you can come up with all sorts of radios, antennas, swr meters, coax, plugs, connectors, microphones, power supplies, external speakers, coax switches, and a whole raft of stuff.

I'm looking forward to conversions of HTs to 10 meters. They sure can do everything a 2 meter unit can (using direct frequencies), and they're a whole bunch cheaper. It should be lots of fun for hidden transmitter hunts, and, when the band opens, I think it would be a real kick to talk from here to California on an HT! SSB CB radios have come down a lot in price for the 23-channel models, but are still fairly high. I believe they'll come down some more. How about a conversion to 29 MHz for 23 channels of AM, with switching to drop it to the 28.5 MHz region for SSB? It's sure going to be fun. So, start scrounging! ■



Heavy-duty rf section.

Box 173
Seven Mile OH 45062

CB to 10

-- part VII: convert a TRC-11

A lot of hams have been talking about converting CB rigs for 10 meter use. I've even seen band plans for use with converted synthesized rigs which retain the same spacing as the CB channels. If you would like to avoid the work needed to convert a synthesized rig, but still want to join the group on 10 AM, try Radio Shack's Realistic TRC-11. It is a six-channel rig, which requires very little effort to be put on 10.

Like most of us who have to watch our pennies, I like to be able to justify buying a new rig. The justification I needed grew out of the results of our first Red Cross simulated emergency test of 1977. Our drill went well, but, during the debriefing, it became apparent that, in a real emergency, our dependence on 2 meter FM simplex channels might lead to problems. We sent three field teams out. Each team used a separate simplex frequency, either 46, 52, or 94, for their own communications. The field control stations also used our 146.37/97 repeater for relay to Red Cross headquarters.

Our later discussions pointed out that we should avoid 94, because it is a repeater frequency and mutual interference could arise. 52 is a nationally recognized frequency and could be crowded. 46 is set aside by the Ohio Area Repeater Council for statewide emergency use. All the frequencies we used had a potential for severe interference in the case of a real emergency, so we talked about possible alternate frequencies. 10 meter AM with a converted CB rig seemed like a natural.

Crystals

The TRC-11 is a crystal-controlled rig and uses separate crystals for transmit and receive. The transmitter uses fundamental frequency crystals. To transmit on 29.3 MHz, get one cut for 29.3.

The receiver is single conversion with a 455 kHz intermediate frequency. The receive crystal frequency is 455 kHz less than the frequency to be received. To receive on 29.3 MHz, get a crystal cut for 28.845 MHz.

I ordered my set of crystals from International Crystal Mfg. Co., 10 N. Lee, Oklahoma City, Oklahoma 73102. They cost $7.90 each. It may be possible to get them for less elsewhere, but, in two separately mailed orders, the crystals have been received within two weeks, so the service was worth any extra cost. Their catalog number for transmit crystals for the TRC-11 is 820308. For receive it is 8203097. Specify catalog number and crystal frequency when ordering. I suggest sending a check when you order — it will save time on processing your order, and International pays the shipping if you do.

Adjusting the Crystal Oscillators

Don't! That's right, you don't need to do a thing to the oscillator circuits. They are broadband enough that they take off with no problems at 10 meters. Before I received my crystals, I wanted to see if I would need to work on the oscillators. The only crystal I had was a spare for my Heathkit SB-301 heterodyning chain, and it was at 29.895, which is above the 10 meter band. I did want to check it out, so I jumpered the crystal into the circuit and tried it into a dummy antenna. It worked with no trouble, so I was sure it would work in the band as well.

Tuning for Output Power

Tuning up for maximum output power on 10 meters is very simple. Before I retuned for 10, I wanted to check how much I was getting on CB channel 9, which comes with the rig. Before retuning, channel 9 had 3 Watts, and 29.3 MHz had about a quarter of a Watt. After retuning for 29.3 MHz, I had 3 Watts there and 1.5 on channel 9.

To peak the TRC-11 for 10 meters, simply adjust the settings of coils L5 and L6 for maximum output, as measured on a wattmeter. All coils are plainly marked on the printed circuit board. L5 and L6 are very near the coaxial connector, towards the left rear side of the unit.

That's all the work you need to do to get the TRC-11 going on 10 meters. Simple, isn't it? Although I have not tried it, I believe the Realistic TRC-9A should convert just as easily as the TRC-11. The TRC-9A is listed as the three-channel, economy version of the TRC-11. It uses the same crystals, and the schematics are nearly identical.

Antennas

As I mentioned earlier, my major use for this rig is as an alternate frequency for emergency use. I did not want to

put a permanent antenna on my car, so I tried Radio Shack's magnetic mount CB antenna, model 21-940, and found that it, too, is very simple to convert for 10 meter use.

The swr is adjusted by decreasing the length of the whip, using the cut-and-try method. I physically shortened the length of the whip to about 73 cm. On my unit, minimum swr was obtained with 66.3 cm of the whip extending above the top of the collar where the setscrew is located. I was able to get the swr down to 1.2/1.

Results

During our second Red Cross drill, Ted White WA8WQC and I tried identical mobile setups using the TRC-11 and model 21-940 antenna. Our results indicated nearly 100 percent usability over a 5-mile path with several hills and numerous buildings. Line-of-sight paths yielded good results at nearly double this distance.

The only problem we encountered was caused by the fact that I have a rather soft microphone voice. Using my usual voice gave poor results, because I was not driving the modulator circuit hard enough. With a little self-control, I find it is easy enough to speak a little louder and closer to the mike to overcome this problem.

If you are looking for a CB rig that is easy to convert for use on 10 meters, and don't want or need to convert a 23-channel synthesized rig, I suggest trying the Realistic TRC-11.

No matter what type of rig you convert to 10, the model 21-940 magnetic antenna from Radio Shack is easily converted to fill your need for an antenna.

With such an easy way of getting on 10 meters AM with a converted CB rig available to you, you no longer have an excuse to miss the action. See you on 10! ■

Battery Backup for Digital Clocks

-- don't miss a second

Joseph W. Long WA2EJT
2406 Maria Blvd.
Binghamton NY 13903

With the addition of a crystal timebase to my digital clock, it began to keep time very accurately — to about a second a month. Unfortunately, my house seems to have more than its share of short power interruptions and blown fuses. An accurate clock is of no great use if it must be reset every few days. Power line independence is a necessity for electronic digital clocks.

None of the ideas on battery power for clocks could be adapted to mine without cutting the foil on the printed circuit board in at least a couple of spots. Since I seem always to manage to slit my thumb along with the circuit board, I like to avoid this approach if at all possible.

The circuit in Fig. 1 should work for just about all clocks, without *any* modification to their circuitry. It amounts to connecting a battery in series with a resistor across the output of the clock supply.

R1 serves two purposes. First, it limits the charging current supplied to the battery while the clock is plugged in. Second, when power fails, it limits the discharge current to about 5 mA. This causes the clock LEDs to extinguish, and the clock runs with no readout, consuming very little power.

Depending on the clock, a different value for R1 may be needed. A little experimentation will determine an appropriate value. Closing S1 will allow the readouts to function on battery power, but the battery won't last long this way, so I used a momentary contact push-button.

Battery life seems to be very long in this circuit. After several months of "field testing," the battery tests as good as new. The trickle charge current it draws seems to do no harm.

Upon power failure, my timebase slows down from 3579545 Hz to 3579515 Hz. This is a change of about 10 parts per million and is equivalent to about 5 minutes per year, or less than one second per day. Most failures last a few minutes or a few hours at most, so this drift is not really any problem. Regulating the voltage at the timebase could eliminate even this drift.

This kind of project is my favorite — it uses only three parts, total cost could not exceed two dollars, it requires no "mods" to existing equipment, it gives real improvement, and it can't fail to work! There is something awfully nice about pulling the plug on your digital clock, plugging it in again and seeing it still displaying the correct time. ■

Roll Your Own QSL Cards

-- originality for rare ones!

The QSL card is as old as amateur radio itself, and cards are as varied as the operators and the gear they use. This article describes a method of photographically home brewing cards that stand out from the pack and are very suitable for that special contact. They also might winkle out that card from the rare DX station.

The technique is simple. Ordinary darkroom equipment is all that you need. The process is based on "lith" and

Photo 1.

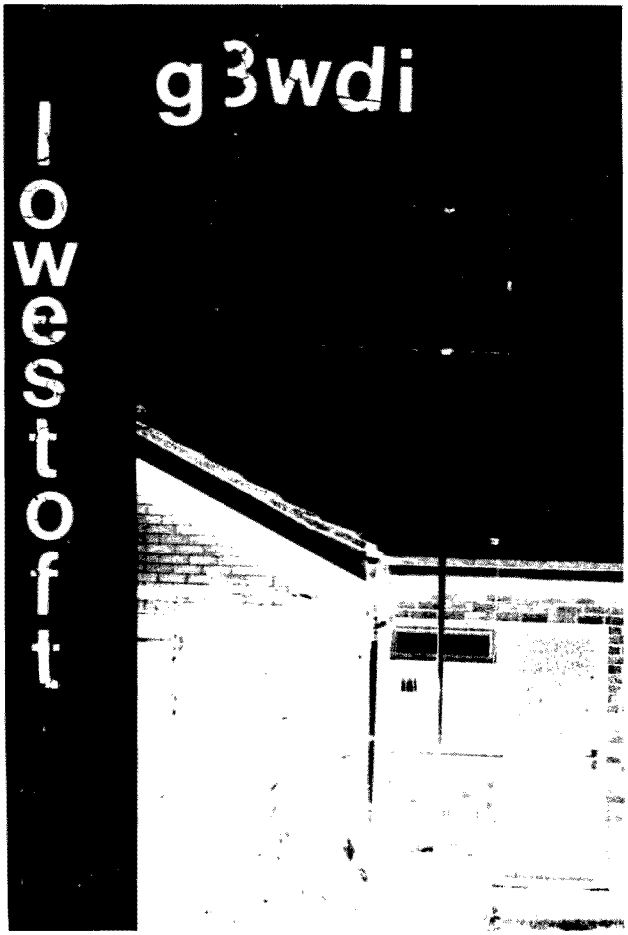

Photo 2.

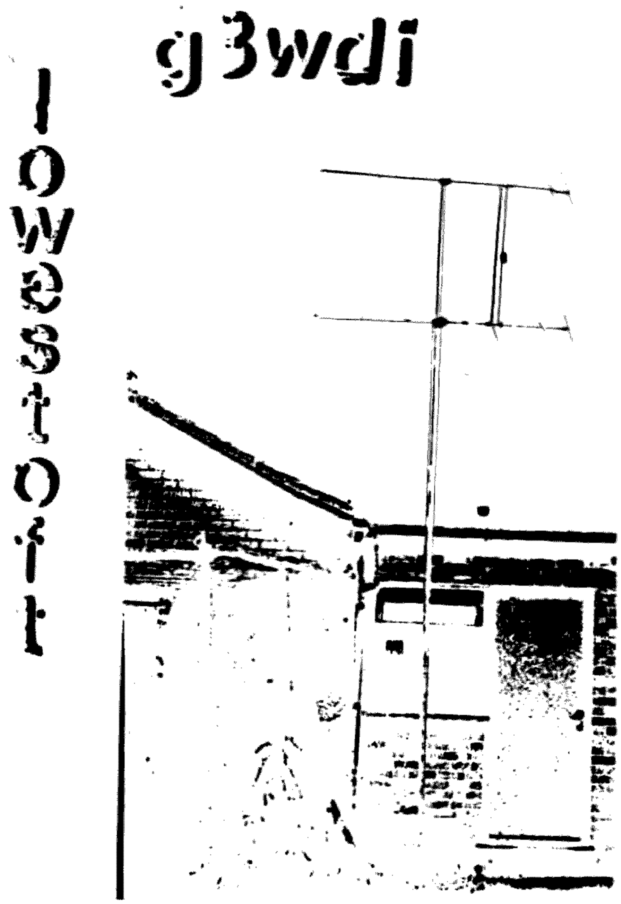

Photo 3.

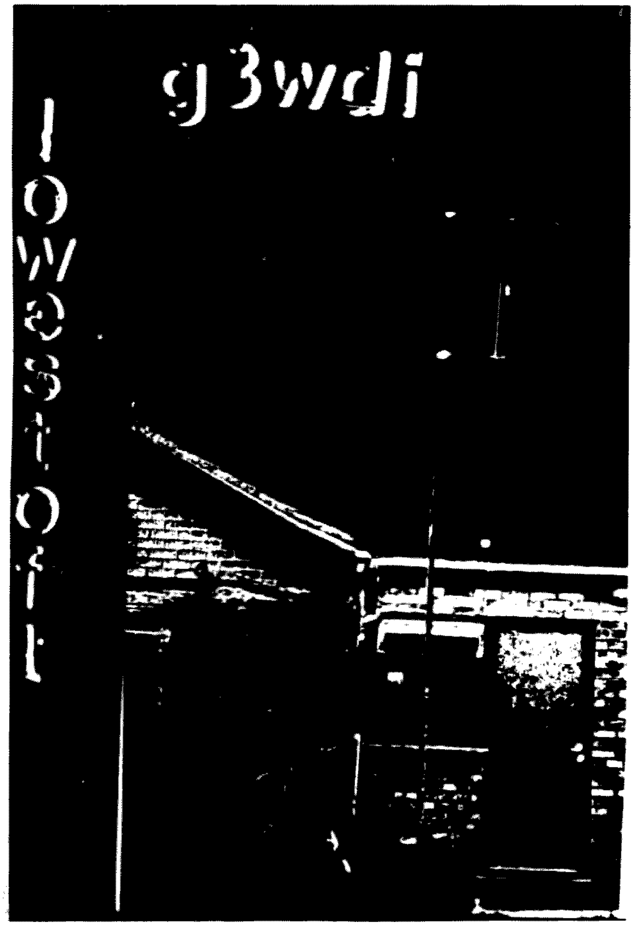

Photo 4.

"line" film, together with lith developer. Advertisements in the photographic press should provide the names of suitable suppliers of these materials.

Lith film is very contrasty and produces pictures in two tones – black and white. Greys on the original picture are thus rendered black or white, according to their density.

A suitable photograph for a QSL card is taken or selected from the negative file. In my case, a photo showing my shack and "antenna farm" was selected. As a normal print this had been less than successful, and it was in the reject file. However, it was most suitable to experiment with. A print of suitable size for a QSL card was made from this negative on a sheet of lith film. The result, after processing and drying (careful use of a hair dryer speeds up the drying), was a large black and white transparency (Photo 1). Using self-adhesive letters, the callsign and other details were added to the picture. In my case, a strip had been masked on the left-hand side for this purpose. A contact negative was then produced on a sheet of line film, and the result is shown in Photo 2.

The negative and positive transparencies are now taped together, slightly out of register, and printed onto a sheet of lith film. The result is shown in Photo 3.

A negative is then produced from this print. Using either the positive or negative, prints are now made onto normal photographic paper for use as QSL cards (Photo 4). In my case, the prints were stuck onto a card, and QSL information was written on the back, since writing directly on the back of photographs is difficult.

Some control over the finished picture can be exercised during the processing – unwanted detail can be blacked out or scratched in. The six over six in my picture was scratched in with a pin, when it disappeared into the sky during processing.

This process of tone separation can be used with filters and colored paper to produce exotic, if expensive, QSLs. At G3WDI these cards will be reserved for special contacts. My first 2m contact with the USA will certainly receive one, while G8HRF in the next block may not! I will watch my incoming QSLs with interest. ■

Glide On Six

-- radio control primer

Radio-controlled model sailplanes and the six meter band were made for each other. We all know how quiet the activity has been on six since the dip in the sunspot cycle has chased all the good DX away. Well, when your twelve-foot-span sailplane is just a dot on the distant horizon, and the rf link that will guide it back home is only 750 milliwatts into a crude rod type antenna, you can appreciate all that peace and quiet. While other types of flying models use radio control guidance, none test the range of the equipment and the vision of the pilot like sailplanes. These planes depend on the rising air currents which drift downwind to sustain them, and they must follow these currents to gain altitude. This results in flights that roam all over the sky in search of lift and gently circling climbs to heights of several thousand feet before a landing in the grass at the pilot's feet.

A modified Windrifter sailplane with transparent yellow plastic covering to show off internal craftsmanship. Span is 99 inches.

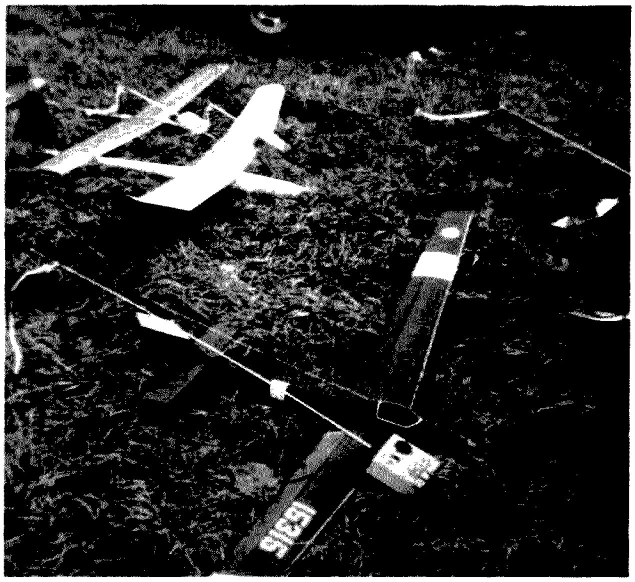
In addition to pleasant Sunday afternoons at the local meadow flying for fun and practice, the coming of summer brings the contest season, with trips to places like Harris Hill near Elmira, New York, and the rolling fields of York, Pa. There, contestants numbering over 100 pilots and their planes gather to see who can stay aloft ten minutes precisely, and then land in a fifty-foot diameter circle for additional points. The majority of these planes are guided by four meter R/C rigs on 72 MHz, requiring a Class C CB license. But since there are only 7 channels authorized for R/C use, much time is wasted waiting for your particular channel to be clear. With 6 to 10 pilots on your channel, the wait can be a long one.

The equipment functions by digital pulse coding of the transmit carrier consisting of a clock pulse and additional data pulses, each of which controls a specific aircraft guidance function. The superhet receiver detects the pulse train and passes it to the decoder, which divides up the various data pulses and distributes them to the servomotors. A pulse width comparison circuit in each servo determines where the servo output arm is in relation to where the incoming pulse says the the pilot wants it to be. The error voltage is fed to a small dc motor which moves the output arm and a small potentiometer until the error disappears. There is one servo each to control the rudder, elevator, spoilers, and captive towhook on the aircraft. Power for operation is supplied by AA size nicads in both transmitter and airborne system, with a usable duration of three hours or so.

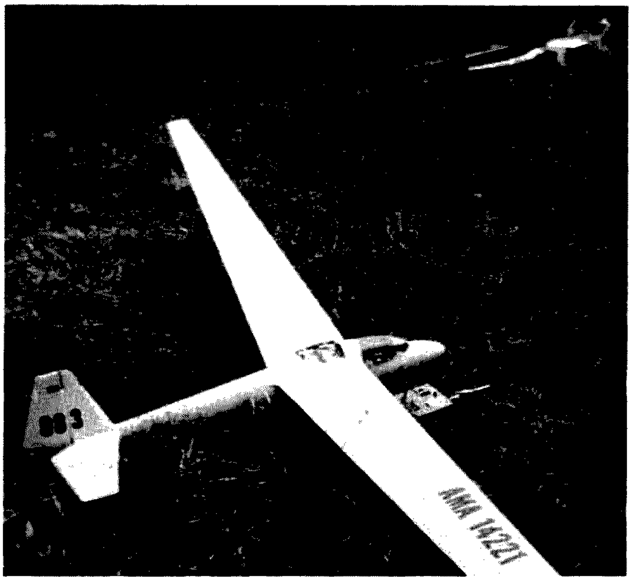
An interfering frequency has the effect of lengthening the data pulses fed to the servos, causing them to run to one end of the output arm and spiral the aircraft into the ground. Loss of radio contact generally has the same effect, in that the receiver agc cranks the i-f strip gains wide open and random noise triggers the servos, all of which used to occur with great regularity when the rigs were on 11 meter CB. Although the 5 frequencies there were not shared with "phone ops," the close proximity and large difference in power levels made those channels unusable.

The resulting crowding in the four meter band has resulted in pressure on the FCC to create a special code-free R/C controller's license class which would allow the pilots of planes, cars, and boats to pursue the hobby with reliable guidance systems. When one considers the damage or injury which could result from the crash of an aircraft weighing four to twelve pounds diving to earth at a hundred miles per hour, it's easy to see why modelers and R/C equipment manufacturers are pushing for space on six meters.

The majority of modelers are like most CBers, in that their interest is in using the rigs, not working on them. There are many, however, who would make fine



A "Hi-Pro" sailplane with molded fuselage and rudder. Wings have large movable flaps to change the airfoil and aircraft speed.

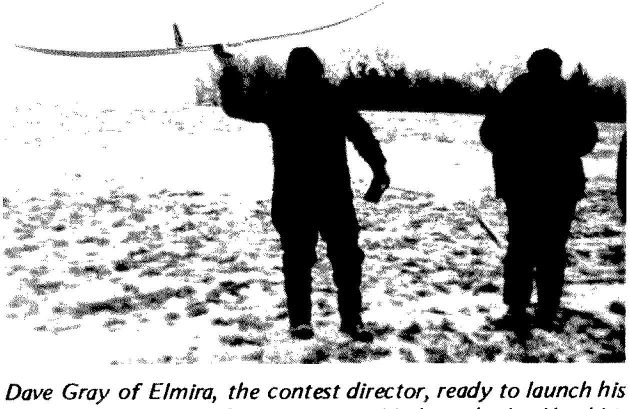


An all molded plastic and fiberglass model of a KA-6 sailplane. Span is 10½ feet, weight is nearly 12 pounds — ready to fly.

amateurs, given some encouragement from local hams. These Class C CBers already have a good record of compliance with FCC rules; indeed, pilots must show their licenses in order to fly in contests. These pilots would find that, in addition to reliable model control, there are some other, rather interesting things which the ticket offers. All they need is a little push in the right direction. And in case you think that big numbers are important, there are over 61,000 members of the Academy of Model Aeronautics, and 3 out of 4 of them fly Radio Control. It would make a significant increase to the amateur ranks if this resource could be tapped.

Which brings us back to that open field in the sunshine and the sailplane flirting with the puffy white clouds. The confidence that a ham rig gives to the sport of glider flying contributes in large part to the pleasure these birds have to give. To see your own creation so at home in the sky while it obeys the smallest movement of your hands makes all the code practice and radio theory sessions worthwhile. And at day's end, when it's time to key up the local repeater for some friendly rag chew, there is no end of ways to work models and flying and infinite descriptions of launches and landings into the conversation.

The next time you're driving down the road and see someone out in a field flying his plane, stop and say hello. He may be a four meter pilot who might like to be a ham or a ham who might give you some stick time on his latest creation. Either way, you can't lose! ■



Dave Gray of Elmira, the contest director, ready to launch his Hobie Hawk glider. This plane is sold through the Heathkit catalog.

Dave Lear WA2ERM throws his Pierce Paragon sailplane off the slope at Harris Hill. The horizon is over 8 miles away and the temperature that day was plus 16 degrees.

More IC-22S

-- add a programming switch

I have found the following modification of the Icom 22S to perform in an entirely satisfactory manner, and to add considerably to the practical capabilities of this machine. As you who already own one know, all of the possible frequencies may be obtained by utilizing various combinations of diodes soldered into the programming board. It follows naturally that, if one could switch in various combinations at will, then all of the capabilities would be possible.

The first problem was where to put such a switch, so that it could be always available and wouldn't be dangling on a cable somewhere. You will see in Photo A where I chose to place this switch. I chose a small, 8-position SPST rocker switch made by AMP Special Industries. This switch plugs into a regular 16-pin IC socket. I bought two of the switches because, should a switch fail with use, I might not be able to find an exact duplicate later.

Photos by Dale Andrews

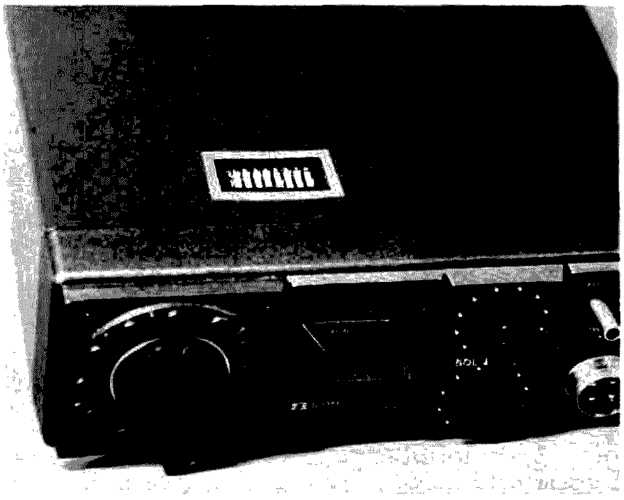

Photo A.

Photo B shows a detail of the switch in place, plugged into a 16-pin IC socket which is mounted on a small piece of 10 x 10 perfboard. The perfboard is supported on two arms, which extend from the small aluminum bracket plate. My aluminum bracket was cut from a junk box – extruded aluminum T-section. A bracket made from any piece of metal would serve just as well.

A look at Photo C shows the bottom of the transceiver with the 8 hookup wires soldered into position 13, in my case. However, you can use any channel or switch position you choose.

There is a ninth wire required, which is attached to the common channel position you may choose, and which goes down to the new switch common bus.

In Photo D, the hookup cables have been pushed aside to expose the underside of the bracket, perfboard, socket, and switch combination. Here you will note that

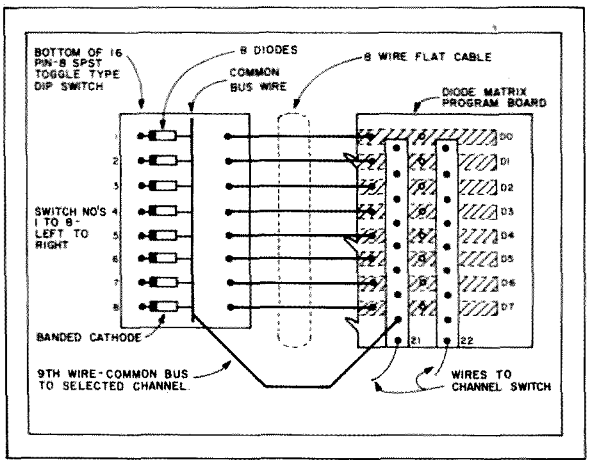

Fig. 1. A portion of the diode matrix program board. The 8-wire cable is attached to channel 21, with the ninth wire connecting the new switch assembly common bus to the program board channel 21 common bus. Note that your dip switches will probably be numbered from 1 to 8. Thus, no. 1 switch will attach to no. D0 program board hole, no. 2 switch to no. D1 program board hole, etc. Thus, when setting up frequency, you must remember to call no. 1 switch D0, no. 2 switch D1, etc. As you can see, this arrangement allows you to switch in any combination of diodes on your selected channel.

a common bare wire was bent and installed between the two rows of socket pins. The bent-down ends of this wire were epoxied to the perfboard. Eight diodes were installed, with the cathode (banded) ends going to each of the eight socket positions on the right, the anode ends going to the common bus wire, and, you can also see, the ninth wire, mentioned above, attached to the common bus. The eight wires going to the program board are attached, one to each socket pin in the left-hand run. Be sure to identify the wire for installation in the proper holes of the programming board.

Construction Hints

The bracket, IC socket, switch, bus bar, diodes, and wiring were all constructed outside the cabinet. The switches, diodes, and wires were all tested for continuity before installation.

The entire bracket assembly was then installed and epoxied to the circuit board and transformer can, as shown in Photo B. Note that this assembly was positioned far enough to the left of the machine, or towards the top of Photo B, to allow access to the meter pilot light. The perfboard is also epoxied to the bracket arms. The socket itself is held by the solder on its pins below.

The bracket must be so sized as to position the top of the body of the switch level with the underside of the transceiver cover plate, allowing the rockers to extend into the opening. After the switch was in place, with careful measuring, a rectangularly-shaped hole was cut in the cover plate. This hole was filed to size, and, as you see in Photo A, I touched up the raw metal edges with paint and used bright red tape to set it off.

I hope, with the above description and accompanying photos, that you will be able to install a similar improvement on your Icom 22S and will enjoy using it as much as I have. Of course, I recommend installing diodes permanently for those channels you use frequently, but this little gadget will get you into all the others when you want to. ■

Amplitude vs. Frequency

-- poor man's spectrum analyzer

Anyone who has used a spectrum analyzer for checking the frequency response of audio or rf filters quickly appreciates its great convenience. Filter values can be changed, and you note instantly the effect upon the selectivity, the change in cutoff frequencies, etc. But, even when using a $12,000 professional instrument, you often find it desirable to switch it into a manual scan mode. In this mode, you turn a single knob, which varies the frequency being fed into a filter under test and simultaneously moves the spectrum analyzer display along its horizontal (frequency) axis. So, as you manually turn the knob, you can note, at any given frequency, the displayed amplitude, or, conversely, you can look for changes in amplitude and note at what frequency they occur.

The manual scan feature on professional instruments was the idea responsible for the simple adapter described in this article. This adapter uses a signal generator and oscilloscope combination. It will not turn them into anything near the equal of a $12,000 instrument, but it does provide an extremely useful method to develop a simplified amplitude versus frequency display on an oscilloscope.

The idea is to turn off the horizontal sweep on the oscilloscope and use an external voltage to move the trace horizontally, at the *same* time that the frequency being fed into the circuit under test is varied. Fig. 1 presents the main idea. If you can simultaneously use one hand to rotate the frequency control knob on the signal generator, and the other hand to rotate the potentiometer connected to the battery, an amplitude versus frequency display is created. Stopping at any given point, you can temporarily use paper tape on the oscilloscope face to mark down the frequency, and thus calibrate the horizontal frequency line on the oscilloscope.

In practice, you need to add a feature to the signal generator so it provides the horizontal control voltage – in order to make the scheme a practical reality, as only one knob is rotated. The practical details for accomplishing this depend upon the equipment being used.

For instance, one setup on which this scheme was tried utilized a 3" scope and a Southwest Technical Products function generator. The horizontal sweep was switched to "external," and the horizontal position control used to move the dot on the oscilloscope screen to the extreme left. Then, by applying a variable dc voltage to the external horizontal input terminals, it was determined that the voltage had to vary from 1 to 9 volts to move the dot completely across the screen. The function generator uses a single

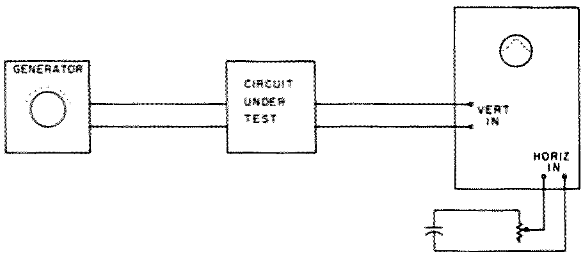

Fig. 1. Basic idea for setting up a manual scan system with a signal generator and an oscilloscope.

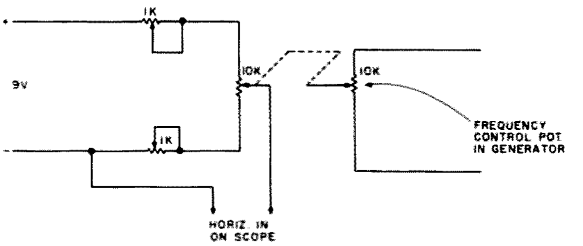

Fig. 2. This simple adapter circuit can be added to an audio-type generator which uses a potentiometer for its frequency control element.

10k potentiometer as a frequency control. This potentiometer was replaced by a dual 10k unit, as shown in Fig. 2. The two 1k PC potentiometers simply allow trimming up of the voltage range covered by the 10k potentiometer, so the dot on the oscilloscope screen moves exactly from extreme left to extreme right, as the generator is turned through one frequency range.

A similar scheme can be applied to other generators, even those using a variable capacitor as a frequency control element. The only problem which must be solved in each individual case is the mechanical coupling of a potentiometer to the shaft of the frequency control element in the generator.

You could add further refinements to the basic idea, depending upon need and the specific equipment involved. For instance, it might be desired to scan across the oscilloscope screen, as the signal generator is only tuned across a narrow part of its frequency coverage on a given band. A higher dc voltage to the control potentiometer will allow the potentiometer to sweep across the required voltage range over less of its rotational range. A better solution is to make the control potentiometer part of a resistive Wheatstone bridge. The bridge can be balanced at any given point, as the control potentiometer is rotated, and the scan across the oscilloscope screen is started at that point. A typical circuit is shown in Fig. 3. Furthermore, by making the dc voltage to the bridge variable, you could expand or constrict the width of the scan. An ultimate embellishment might be to add a variable gain, dc voltage amplifier to the output of the bridge circuit. The display, which you see on the screen as a circuit is tested, will be a vertical line, changing in amplitude both above and below the center line on the oscilloscope as it moves across the oscilloscope screen. You can adjust the vertical position control on the oscilloscope, so only the top "half" of the display shows. This does get a bit closer to a real spectrum analyzer display. But, depending upon the circuit under test, it may hide negative peak clipping taking place in a circuit.

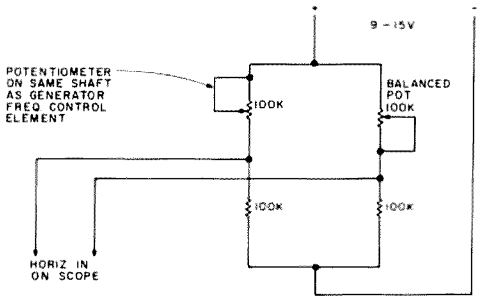

Fig. 3. Bridge circuit to allow better control over setting point on signal generator scale where scanning starts across oscilloscope.

You should neither overestimate nor underestimate the usefulness of this adapter. It displays only a simple plot of amplitude versus frequency for a circuit under test. Many other things, such as phase shifts, might be taking place in the circuit which you would not be aware of. Nevertheless, for someone who likes to experiment or needs to adjust simple tuned circuits or filters, this simple adapter will give you a little and very useful hint of what life would be like with a $12,000 Hewlett-Packard spectrum analyzer on your bench. ■

How About An Auto CQ?

-- generate some 10m activity!

How many times have you tuned across 10 meters and wondered if it was really dead? I used to sit down and call CQ for a while, until I got tired of it or else got hoarse. Wouldn't it be nice if I could call CQ automatically? Then I could spend the time more constructively, and I just might beat a hole in the band!

I could use a tape and operate VOX[1], but this would be plagued by nuisance tripping as I shuffled papers or stumbled around the shack. No — I must have a more sophisticated solution! And so was born the tone-actuated, tape-driven auto CQer described below.

Certain requirements for this magic machine were immediately set forth:

1. The device must be immune to ambient noise.
2. Any tone used must not be transmitted.
3. The circuitry must include capability to make the control tape.
4. The automatic operation must be easy to cancel.

To make all this happen, the block diagram shown in Fig. 1 shows briefly how the auto CQer works. A tone on the tape is detected and clocks a flip-flop. The flip-flop, in turn, drives a relay to activate the PTT line in the transmitter. A 4 kHz tone was chosen because it falls about an octave above the bandpass of SSB transceivers available today and, thus, is not transmitted. The tone from the tape on playback is first applied to an active filter, A1, whose narrow bandpass is centered on 4 kHz. The output of this filter is rectified by CR1 and averaged by C2. The resulting dc voltage is fed to comparator A2, whose output clocks the 948 flip-flop for on-off control of the PTT line.

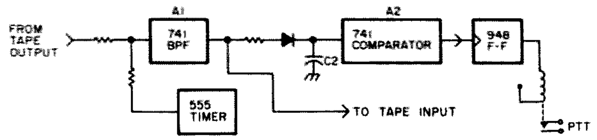

Fig. 1.

The result of this is that the state of the 948 is changed only when a tone is detected. The transmitter is thus protected from nuisance tripping.

Basics

The circuit shown in Fig. 2 has two modes of operation. The first develops the tone and mixes it with the microphone audio to be recorded. The second mode, playback, detects the tone from the playback audio, as outlined above, and activates a flip-flop to control the transmitter.

In the record mode, the 555 tone generator develops a 4 kHz square wave. This is keyed by unshorting the timing capacitor, C1, with S1. The square wave is fed to an active filter A1. This 4 kHz active bandpass filter provides a clean sinusoid to mix with the voice audio for the recording.

In the playback mode, the audio from the recorder is fed into the active filter, and the tone is separated and detected. The rectifier/filter on the output of A1 also integrates or sums the tone. This means that the tone must be detected and remain so for a certain minimum time. After about a second or so (depending upon the playback amplitude of the tone), the reference threshold of the second 741 (A2) is reached, and, acting as a comparator, it flips from a high (+) to a low (≈ 0) output voltage. This voltage clocks the flip-flop to its opposite state. The output of the 948 drives the transistor, which in turn activates a small relay to key the transmitter PTT line.

To prevent audio feedthrough to the transceiver speaker, the audio to the mike jack is shorted to ground by C3 when Q2 conducts during receive. This short is released in transmit to pass audio on to the mike jack on the transmitter. The normally open side of SI serves to reset the 948 flip-flop, just in case the PTT line gets stuck in transmit. S2 shifts audio control from the auto CQer to the station microphone. Just remember to operate S2 when you answer someone!

Building It

I built the circuit on

vectorboard, and the layout is not critical at all. However, I have found that if the part locations follow the way the schematic is drawn, it is a lot easier to troubleshoot later on. In addition, inputs and outputs fall to the edges of the board more readily.

A word about parts: The 741 operational amplifier was chosen for its ease of use and procurement. The 948 flip-flop, though an old DTL device, is hard to beat at 20¢ from James Electronics.

Care and Feeding

My audio input is from a compressor which puts out .25 volts p-p. The mixing resistors are set to divide this audio down to the proper level for the recorder input. The same goes for the tone level. It may be necessary to adjust R2 so as not to overdrive the tape recorder. The speaker output of the tape recorder feeds the audio to A1. The audio level at the output of A1 determines if, or at what time delay, the comparator, A2, switches. A little experimentation may be necessary here to determine the required audio output level for a one or two second delay. This delay provides further noise immunity. If a scope is available, 2.5 V p-p at A1 is sufficient. Any more output volume than that may well overload and distort the voice audio into the transmitter.

Set the tone frequency by measuring the dc voltage on C2. Use a VTVM or other high impedance voltmeter, and adjust the value of R1 for maximum deflection. The response is slow, so wait for the voltage to stabilize. The voltage should be greater than about 0.4 volts dc for the comparator to operate.

The comparator has positive feedback around it to provide a noise margin of 90 mV, which results from the hysteresis. This means that with a threshold of, say, 0.4 volts, the input voltage must get to 0.445 V (0.4 + .09/2)

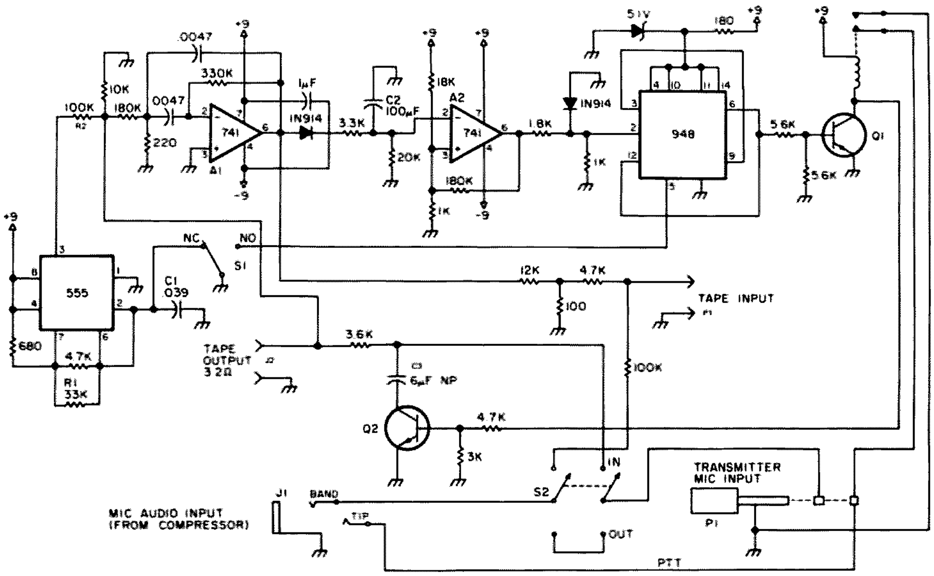

Fig. 2.

before the output changes state. The reverse is also true. If the input starts above 0.445 volts, it must fall below 0.355 volts (0.4 − .09/2) for the output to change.

A word of caution in substituting parts: The 948 flip-flop clocks at a threshold voltage and is, therefore, not dependent on the rise and fall times of its clock signal. A JK TTL flip-flop like the 7473 should be clocked with a fall time of, at most, 30 ns. The output slue rate of the 741 is much too slow at 30 μs. The transistors, on the other hand, can be any common NPN. The 2N2222 is a good choice because of its price and availability.

My intent is not to limit substitutions, but rather to provide a starting place for the experimenter. A little thought given to certain substitutions will save a corresponding amount of grief later on.

The simple power supply is shown in Fig. 3.

How To Use It

The first step to using the auto CQer on the air is to make the tape. Plug the tape input, P1, into the mike input of the tape recorder and a microphone into the audio input on the CQer. Now you're set to record the tape.

You will need about 3 seconds of tone (just to be safe) to activate the flip-flop, so plan accordingly. I made my tape on a 30-second CQ, 30-second listen program, but this is offered only as a starting point. Just remember to give the tone at the beginning *and* at the end of the CQ.

To use the CQer is even easier. Plug the transmitter mike input, P1, into the transmitter and the station mike into J1. The tape recorder speaker output plugs into the tape output jack, J2. Set the playback volume to trip the PTT in about 1 to 2 seconds, but not so high as to overmodulate. If the recorded audio of tone and CQ are of the same relative level, it will be possible to achieve the right balance of playback volume and mike gain on the transmitter.

On the air, set S2, punch up playback and sit back and relax. Even though the band may be dead, at least all you're doing is wearing out the tape and not your vocal cords!

To answer a call, just switch S2, shut off the recorder (you might do this with another position on S2, if your recorder is equipped with a remote jack), and operate your rig normally.

The reliability of this machine has been excellent. After about 18 months of use on the air, the only problem has been when the recorder batteries run low, and the tone frequency shifts and goes undetected. It is for this reason that the reset switch, S1, was included, just in case the transmitter gets stuck.

Since I've built this device, I can't imagine not having it. It actually is my way of having a beacon on 10 meters, to which I am so devoted. You can hear what is being transmitted, and so can catch it if anything goes haywire. I hope that the utility of this machine will provide you with more time to really enjoy this great hobby of ours. ■

SSB For the "Frog"

-- tame the croak

The Yaesu FRG-7 is a remarkably good receiver for "all-wave" reception of AM or radio telegraphy. It falls short, however, of being good for SSB reception, unless you have one of the new models featuring a fine tuning control. This article is addressed to the owners of FRG-7s having serial numbers between 502001 to 505999 or between 060001 to 072000. If you have one, read on.

For $7.25 you can buy a modification kit from Yaesu. I did. You shouldn't. Why? Except for matching knobs, you can buy the needed parts (if you can't find them in your junk box) for a small fraction of the cost of the modification kit.

You need just two items. One is a small variable capacitor, small in physical size as well as in capacitance. The latter should be somewhere around 5 pF – not much more, not much less. It should have a shaft about one inch long (2.5 mm) and must be of the single-hole mount type. The other item is a knob to fit the shaft of the variable capacitor. If you have a choice, get one with a dot or other type of position indicator. If you're a purist, buy a replacement for the volume control of your FRG-7. It's a bit large, but it'll match.

Now you're ready to dissect your FRG-7. You'll need a Phillips, or Reed Prince, type screwdriver and a ¼-inch nutdriver. With the latter, take out the two screws along the bottom rear lip of the cabinet. With the former, remove the six small screws around the front edge of the cabinet and the one small screw at the top of the rear edge. Now, slip the chassis forward out of the cabinet.

Use a small, blade-type screwdriver to loosen the setscrews, and then remove all the control knobs. Then use the Phillips screwdriver to remove the three screws retaining the escutcheon plate.

With the slimmest soldering iron you can find, unsolder the two wires leading to the "Lock" lamp. Then remove the nut from the "Mode" switch. Next, take out the four screws that hold the external front panel to the inner one. Slip off the panel, and prepare to do some precise measuring.

If you have a metric rule, as everyone should, use the following figures. Otherwise convert them to inches.

From the right-hand edge of the front panel, measure in 14.4 cm. Then, from the bottom edge, measure up 6.2 cm. Mark the intersection, and drill a very small hole, barely through the panel. Pause there, turn the panel over, and carefully cut out the padding around the hole you just drilled, removing enough to leave a clear spot about 18 mm in diameter, centered on the hole in the panel.

Put the outer panel back on the receiver, and run the drill through the hole just far enough to clearly mark the spot to drill through the inner panel. Remove the outer panel, and drill the inner one. Make a hole just large enough to mount the variable capacitor. The one I got from Yaesu required a 7.5 mm (about 5/16 inch) hole. Note that you'll need a semicircular bushing between the capacitor and the panel; the speaker mount intrudes into the space needed for the capacitor. This is easily made.

While you're drilling, enlarge the hole through the front panel to 14 mm (about 9/16 inch).

After you've mounted the variable capacitor and screwed tight its retaining nut, replace the front panel and also the escutcheon plate. Don't forget to reattach the two wires to the "Lock" lamp or to replace the nut on the "Mode" switch! Very carefully set the plates of the variable capacitor to half mesh. Then attach the control knob, having the dot or pointer straight up. Replace all control knobs.

If you bought the Yaesu modification kit, *do not* install the 33 pF capacitor in place of the 51 pF capacitor C-458.

Note the printed circuit board just behind and a bit to the right of the variable capacitor you just installed. All the parts you'll be concerned with are located close together on the corner of the board that's next to the variable capacitor. The parts identification numbers are marked on the board, but you must look closely to see them. Locate T-403, a transformer in a tiny square can. Then spot TC-403, an adjustable capacitor just to the left of T-403 and a bit behind it. Look a bit behind TC-403, and spot the two terminals to which are attached wires running down under the chassis to the main variable tuning capacitor. The rearmost of these two terminals is the "ground" one. The foremost one is "hot."

Now run wires from the

variable capacitor you installed over to these two terminal posts, being careful, of course, to hook the rotor to the rearmost and the stator to the foremost!

If you bought Yaesu's kit, now you're ready to file the provided instruction sheet very carefully in the wastebasket, and get out the instruction manual that came with your FRG-7. Turn to page 12 of your manual. Look under the heading "Main Tuning Dial, T-403, TC-4D3." I quote:

"The following alignment should be done after warm-up of the receiver.

"Set the dial hairline to the center of the dial window. When the main tuning dial is rotated until it stops over the 1000° scale mark, the delta mark should be within 5 mm of the hairline.

"Set the Mode switch to lsb and the MHz dial to 0°. Set the main tuning dial to 1000°; a beat tone *may* be heard. Adjust T-403 until the beat is heard and is brought to zero beat. Set the main tuning dial to 0°, and adjust TC-403 for zero beat. Repeat these two procedures until zero beat is obtained at both 0° and 1000°."

The procedure in the manual works quite well. The one contained in the instruction sheet is utterly worthless!

The addition of the fine-tuning control makes the FRG-7 quite easy to use for SSB reception. More selectivity might be desired. Should you feel you need that extra selectivity, read the article by Ron Risher VK3OM in the March, 1977, issue of *Amateur Radio*. He describes a nonbutchering operation, one using a spare deck on an existing switch to select an alternate filter, consisting of four cascaded SFD-455-B solid state filters linked by small coupling capacitors. I haven't tried it, but it sounds intriguing! ■

Beat the Books

-- study hall special

There comes a time in every kid's life when he wants more out of study hall than just studying. My time came about two weeks ago, and being a ham, I naturally wanted to do something with radio. I knew from the start that it would be hard, for Ma (as we had nicknamed our teacher) had an eagle's eye that could weed out a well-hidden game of solitaire in a class of 55. Anyway, I began to think of ways to outwit Ma and still have fun. A code practice oscillator was out, as I had already bored myself to tears tapping out English assignments on the desk with my pencil. Of course, the ultimate goal would be a QSO with a portable transceiver, but it seemed a little far-fetched at the time. But the more I thought of it, the more feasible it sounded. The walls of the study hall were made of wood and plaster, easily penetrated by radio waves.

I began my search for a suitable battery-powered QRP transmitter. This proved easy, for the second magazine I looked at was the January, 1977, issue of *73*, which contained a dandy little portable transistor QRP transmitter, easy to construct, and, from the description by the author, pretty potent at getting those waves into the sky.

Having decided on a transmitter, I was then faced by the dilemma of what to house the thing in. It must be inconspicuous, but large enough to handle the transceiver and batteries, which amounted to quite a load. I decided on a card filing box, for these were a fairly common sight at school.

For a receiver, I decided on a converter for a broadcast band radio with an earphone attachment. I wasn't taking any chances with Ma, who had the ears (and the temperment) of a wildcat. The pocket radio conveniently fit inside the lid of the card file box with a bit of double-sided foam tape.

I then constructed an aluminum chassis to fit the box, and on this I mounted the transmitter, which consisted of a transistor oscillator and a tuned circuit tuned to 40 meters, the chosen band. The BC converter was a bit tougher, as a bfo had to be constructed to take in the signals without the tones sounding like pure ac.

But eventually everything was straightened out and ready for initial testing. I plugged in a 40 meter crystal, plugged in a dipole, and flipped her on. A little tuning later, and the receiver began hauling in all sorts of signals, and with my station receiver, I roughly calibrated the dial. The transmitter really blared away on my station transceiver. Finally, after a grueling two hour slop-together job, all was ready. The next day, after breakfast, I tucked away a tiny earphone, grabbed my 98¢ "Junior" code key (I wonder how many old-timers still use those things), snatched a long wire antenna with a phone plug at one end and an alligator clip at the other, and smuggled the whole mess out the door past my mother.

When I got into study hall that day, I sat in the back row where there was a radiator for a grounding, and connected the transceiver. I didn't have the slightest idea about where to connect the antenna, and glanced around for a support. I ended up connecting it to a vacant desk three seats to the right. I ran the earphone up my shirt. Even Ma doesn't have x-ray vision. I turned everything on, and immediately zeroed in on WB9––– calling CQ, S9. I answered him, hoping the key clicks (audio, not rf) wouldn't be noticed. To my great joy, he came back TNX, OM. UR RST IS 369. NAME IS. . . Immediately my mind soared. Mini rotary beams! DX! SSB! Maybe later, that W8 is really giving me QRM. I might lose my first study hall QSO! ■

Clocking Those Clock Kits

-- check out the MK-03!

The current plethora of digital readout clock kits makes it very difficult for the potential buyer to decide which is the one best suited for his needs. One of the many that are presently available, and which has not been advertised to any great extent by its suppliers, is the MK-03 Aircraft Clock-Timer kit. Bullet Electronics, the kit maker, may be underestimating the potential popularity of this kit. Its many unique features place it apart from others that are available.

Although this clock may have its primary application in cars, boats, and planes (FAA certification may be required), its compactness and features have a number of good applications in the ham or CB shack. OSCAR buffs will find it ideal for alerting them to the next pass, as the quick-setting alarm feature enhances this type of use. Power supply voltage requirement is 9 to 18 volts dc; thus a simple base station power supply is all that is required for fixed use. A power supply for this purpose is available from the kit supplier.

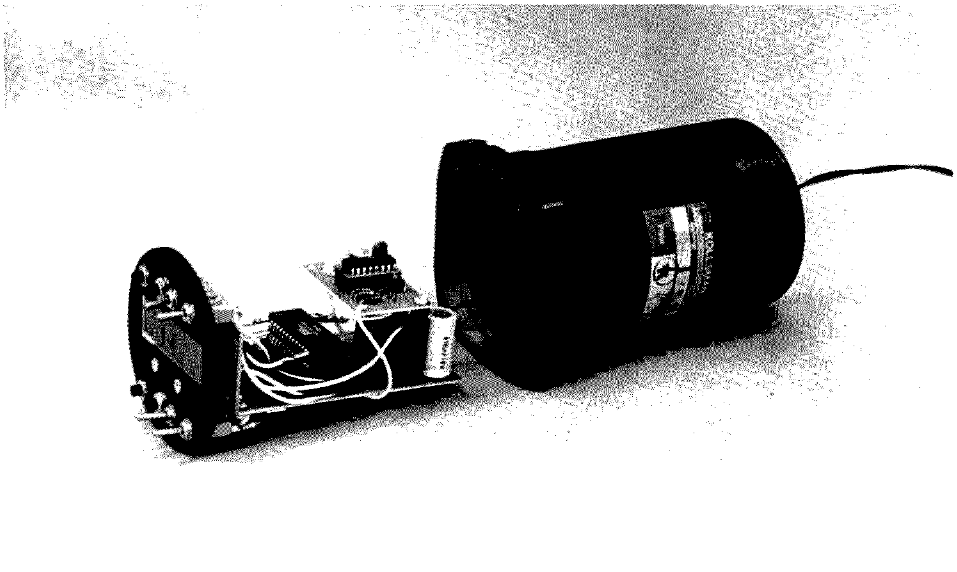
The kit, as received from Bullet, contains all parts, except switches and a case, to make a working clock-timer. The lack of case and switches allows you to design the enclosure and panel to suit your exact needs. In my case, the objective was to place the entire assembled unit inside a standard aircraft instrument case for use in a sailplane (glider). This was an old altimeter case, as shown in the photo. Doing this required a fair amount of ingenuity, but the result was very satisfactory. Others may wish to use a larger, less difficult package, and, if panel space is available, as at a fixed station installation, larger switches and layout would be more convenient.

The printed circuit boards for this kit include a six-digit readout board (allowing the FND-70 0.5-inch readouts to be directly soldered to the board), a main clock-timer board, and a timebase board. The latter uses a ceramic resonator as its standard, and a CD4060 CMOS as a 14-stage binary counter/oscillator. The oscillator frequency is divided by 2^{13} to produce the output frequency (50 Hz in this instance). My scope showed the output of this oscillator to be an excellent 4.9 volts square wave. Bullet advertises this oscillator kit as being available as a separate item, incidentally.

The main clock-timer board is standard, as far as digit drivers are concerned. However, the board uses two 50252 28-pin ICs, stacked in parallel, to accomplish the separate clock and timer functions.

The clock chip (bottom) operates as a normal 24-hour six-digit display clock. The timer chip (upper) operates as a 24-hour six-digit display elapsed time indicator. As received, the two chips are piggy-backed together, with the pins, which are paralleled in operation, already soldered together by the kit supplier. No soldering to the pins is required, as the dual IC is eventually installed in a DIP socket, which the user has previously soldered to the board. Connections to the top chip which are required are made with slip-on connectors (not supplied).

Components in the kit appear to be of good quality, and, for the most part, are



Bullet MK-03 Clock-Timer completed and ready for installation in aircraft instrument case. Digital readout board is attached to plastic escutcheon.

"house-numbered" items, indicating that they were probably not to the manufacturer's standard, but are quite satisfactory for general use. Two of the FND-70s, as received with the kit, had one open segment. Otherwise, all parts were excellent. All resistors for board mounting were precut and bent to radius, and all diodes and transistors were cut to length for mounting and soldering. Material was provided to assemble a toroid choke, in the event that the unit is to be powered by an ignition-type engine power source. In addition, an input protection diode is provided to prevent an incorrect polarity connection from damaging the unit.

Circuit board solder plating tended to have a dull appearance, and occasionally some difficulty was encountered in preparing satisfactorily soldered connections. This was particularly noticeable when working on the readout board, which has rather closely spaced traces that compounded the problem. Manufacturers would be wise to increase the cost of a board by a few pennies to provide good traces and well-plated boards, in order to insure customer satisfaction and trouble-free operation.

The many switches required for full operation of the clock-timer increase the complexity of the wiring external to the board, but they do not create any problems, if care is taken in routing the leads.

Instructions and diagrams supplied with this kit are quite complete, with ten pages of information. Nevertheless, they must be read thoroughly prior to constructing the kit, in order not to overlook some item of importance, not necessarily mentioned where you think it might be in the text. There was a schematic error in my instructions, which may be corrected now, as this has been brought to the attention of Bullet.

Upon completion of the entire assembly, I used a 9 volt transistor radio battery to test the clock-timer (this is not recommended for other than testing because of a .085 A current drain). The unit operated immediately, with no difficulties whatsoever, and it was fun to be able to run through the interesting list of functions that this clock is capable of performing.

The fact that the timing and clock functions perform independently of each other permits using the features of one without interfering with the ongoing action of the other. For instance, the elapsed time function, which displays hours, minutes, and seconds, may be started, held, restarted, or reset to zero while the "real-time" clock continues its normal operation, undisplayed.

The switches may be connected to perform the following listed functions. The display switch may be switched either to the off position (in which case all functions continue, but are not visible), or to display either the timer action or real-time clocking.

Real-time clock – Hours set, 10-minute set, minutes set, alarm enable, and clock display mode (shows either real time or what the alarm set time is).

Timer – Start, hold, and reset.

An additional feature may be used, but was not necessary for my application. This is a photo intensity input to the clock chip, which will reduce or increase the display intensity, dependent upon the ambient lighting.

As a full-function device in the shack, or mobile anywhere, this clock-timer appears to have all the requirements, for a modest $26.95. Bullet Electronics, P.O. Box 19442, Dallas, Texas 75219, is the supplier. ■

Digital Signal Source

-- TTL signals for counters, micros

In playing with logic circuits over the past few years, I repeatedly encountered the lack of a suitable signal source. Several things were tried, including squaring circuits on the wide-range rf generator and several pulse/function generation units, with only marginal success. Recently, while working on a frequency synthesizer, an idea occurred that after breadboard construction seems to be the answer. Development of this idea as outlined below will result in a square wave signal source covering from 20 MHz down to subaudio in fully tunable decade steps. For my purpose, it has proven to be an ideal unit for experimenting with amateur radio applications of TTL and CMOS logic.

Theory

The basic idea as presented in Fig. 1 is for a tunable oscillator in the 10 to 20 MHz range with switchable decade dividers for the range selection and switchable binary dividers for band selection. The resulting frequencies and time constants are listed in Fig. 5.

Construction

Fig. 2 is the oscillator which I used – others would do as well. Try your favorite . . . just be sure the output is adequate to drive the digital buffer. Drive requirements to the first TTL stage can be cut down by biasing that stage into its linear (?) range with a 2.2k resistor to ground as indicated in Fig. 2.

Fig. 3 represents the power supply circuitry and is self-explanatory. Fig. 4 includes the dividers and output circuit. Construction is straightforward with few precautions. It would be wise to keep all divider-to-switch wires separated from each other slightly (just don't bundle them all together in a cable harness). Run a separate power and ground lead for each IC. That way you need only one bypass capacitor on the common +5 volt and ground point.

My final version has a calibrated dial and tunes with a 20:1 VFO drive. However, I find it more convenient to cable the output to my digital counter for direct frequency readout.

I wired the VFO portion using point-to-point technique on insulated standoffs. The divider is on perfboard and wired with wire-wrap pencil.

Summary

While my unit is just the basic generator, hindsight has indicated many additions which might enhance its operation. Some of the possible

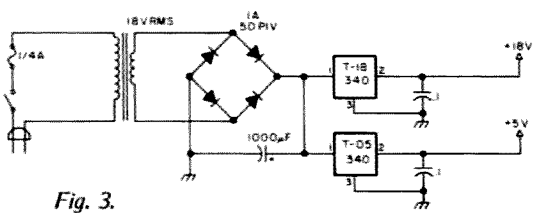

Fig. 3.

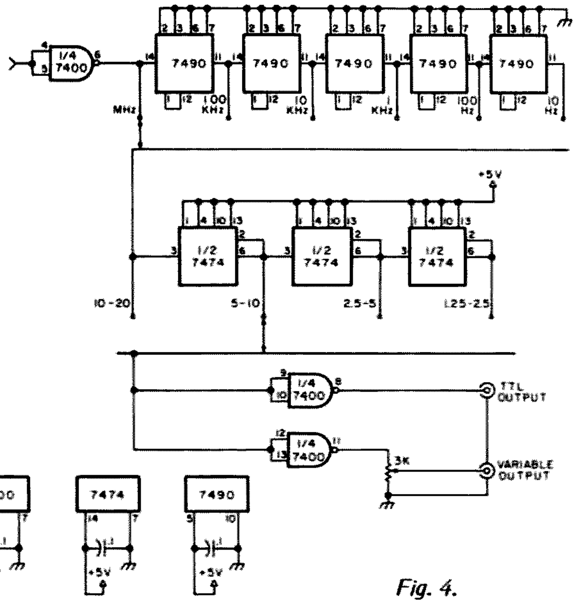

Fig. 4.

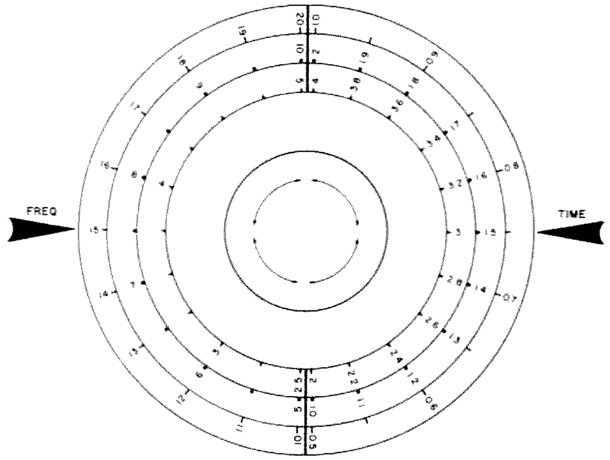
additions and their applications are listed below:

1. FM the VFO with an audio oscillator and voltage variable capacitor for working with FM receivers, phase detectors, or PLL circuits.
2. Switch the divider chain from the internal VFO to an external input jack. This would allow signals from external sources to be divided.
3. Switch the divider chain input between the internal VFO and a crystal oscillator to generate harmonically-related standard frequencies.
4. Add a second buffer and output circuit for opposing polarity outputs.
5. Run the output through a one-shot multivibrator for thin-line pulse generation.

In case you use this as an rf generator for general purpose work, you might be interested to know that the square wave output generates strong harmonics beyond 2 meters! ■



Frequency	Time	Frequency	Time
10-20 MHz	0.1-0.05 uS	10-20 kHz	100-50 uS

Regenerated CW

- - CW: as you like it

One of the useful accessories to a receiver for CW operation is a device that will key an audio oscillator in accordance with an incoming CW signal. Then one doesn't have to listen to the original CW signal with its background noise and QRM, but can listen to a clean, locally generated audio signal. This sort of device also provides a bonus feature useful with transceivers having no tunable bfo and where one must listen to a CW note determined by i-f filter characteristics and the crystal-controlled frequency of a product detector. Usually, these transceivers are set up to produce CW notes of from 600 to 900 Hz. But not everyone enjoys listening to a constant pitch CW note for extended periods. However, if the incoming CW keys a local audio oscillator, one can vary the pitch of the tone actually being listened to without affecting the correct tuning of the transceiver.

Such local oscillator keying devices for CW reception are not new. Many designs were built in tube-type days and worked quite well. The problem was that such a device got to be rather elaborate and costly with tubes. Such devices usually consisted of a sharply tuned audio filter followed by some audio amplification. Then the audio signal was rectified and used to operate a sensitive relay. The relay simply keyed a local, variable frequency sine wave oscillator which one then listened to as it was keyed instead of the original signal.

Using solid state devices one can, of course, duplicate the original circuit idea. Sharp, single frequency audio filters can be built using the commonly available 88 mH toroid coils. The filtered signal can be amplified by an audio IC stage, rectified, and the dc signal used to control a reed relay. Any desired local oscillator can then be keyed by the relay.

This article presents a similar but slightly different approach by taking advantage of some of the new phase locked loop ICs on the market. Basically, a phase locked loop is used to serve as a tunable audio filter and LED switch driver. The LED switch in turn activates a variable frequency tone oscillator. The circuit is compact and inexpensive. Its only disadvantage is that it must be more carefully tuned than a circuit configuration using a passive input filter. But this is mostly a matter of becoming used to the adjustments involved, and it is not a tedious affair. Only parts of the basic circuit can be used if one further wants to simplify the device. For instance, the PLL tunable audio filter can be replaced by a passive LC filter. This eliminates any tuning but takes away from the versatility of the unit since the receiver tuning controls then have to be adjusted so the CW beat note falls in the filter passband. Still another alternative, if one has a receiver with already good i-f or audio signal selectivity but gets tired of listening to the hollow ringing sound of such a receiver, is to use only the LED and audio oscillator portions of the circuit. The LED is driven by rectified af and activates the audio oscillator. Each of these application variations is discussed in the following paragraphs.

Fig. 1 shows the diagram of the 567 PLL tunable audio filter. The 10k potentiometer by pin 5 serves as the frequency tuning control, and the 10k potentiometer in the

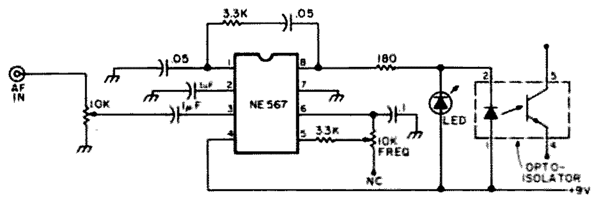

Fig. 1. Tunable audio filter uses a 567 PLL IC. The optoisolator can be a Sprague ED702 (many other surplus units at lower cost will also suffice). A multi-turn potentiometer for the 10k frequency adjustment control will facilitate adjustment, but a regular potentiometer with a large knob will also work.

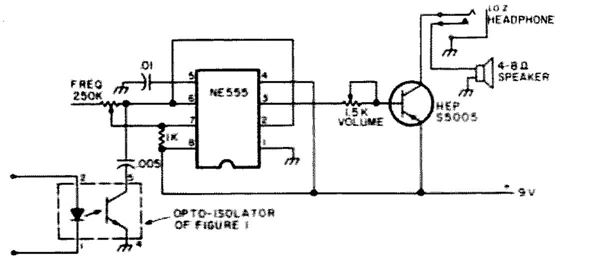

Fig. 2. NE555 audio oscillator/amplifier which can be driven by the PLL tone filter of Fig. 1. Note the simple but effective S5005 amplifier stage for the square wave output of the 555.

input lead is used to adjust the input level. This extra control is provided since one will usually initially monitor the receiver's audio output aurally until the filter locks into place on the incoming signal. The af input level (from a headphone jack, for instance) that provides good aural level may overload the PLL. Hence, the 10k input potentiometer is necessary. The bandpass of the filter varies with the input voltage level, and careful adjustment of the frequency and input level controls is needed. It is best to practice first with steady tone input signals rather than a keyed signal. The output of the PLL drives a regular LED and an LED optoisolator. The regular LED simply serves as a visual tuning aid to indicate the PLL is locked on to the incoming signal. Of course, it will lock on to any input frequency to which it is tuned (or even harmonics of the input signal if it is overdriven). However, by providing a switch to go back and forth between the audio input and the output of the keyed audio oscillator stage, confusion will be eliminated. The optoisolator LED is used as a switch to key an audio oscillator stage. It can be used to key any desired oscillator. Some operators prefer a sine wave signal, while others find a harmonic-rich square wave more interesting to copy.

Fig. 2 shows an NE555 oscillator/amplifier which can be keyed by the circuit of Fig. 1. The circuit is straightforward and provides both variable frequency and volume control. It will drive directly a small loudspeaker or low impedance headphones.

Fig. 3 shows some additional circuits which can be used with the circuit of Fig. 2. Fig. 3(a) shows a passive 900 Hz audio filter and rectifier which can be used to drive the LED optoisolator to key the NE555 oscillator. The PLL stage of Fig. 1 is not used and the 900 Hz filter is driven directly from the speaker output of the receiver being used. Fig. 3(b) shows just a rectifier circuit driving the LED optoisolator. This ultrasimple circuit can be used when the receiver has adequate selectivity and it is only desired to key the NE555 oscillator. The optoisolator approach in the foregoing circuits may seem a bit elaborate for a simple switching function. However, they allow versatility in keying various oscillator circuits and if purchased in untested lots can be very economical. The pin arrangement of most types is as shown in Fig. 1. One can locate the basic elements with a VOM and use a 1.5 V battery with a series 47Ω resistor to see that switching action takes place when the LED is activated. ■

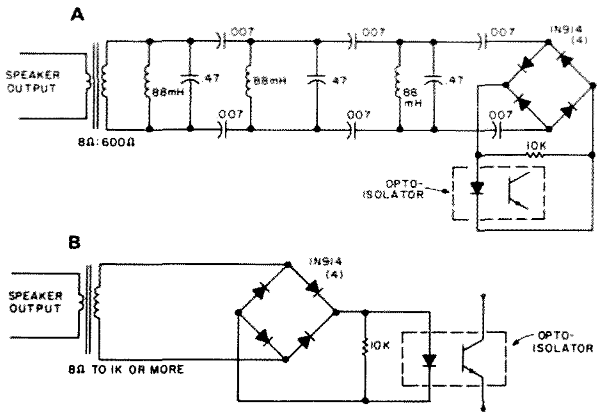

Fig. 3. Two other circuits that can be used to key the NE555 oscillator without using the PLL circuit of Fig. 1. Mylar capacitors should be used in (a). The .007 capacitors are paralleled .005 and .002 mF units.

Al Klein W2PMX
206 Harrison Avenue
Miller Place NY 11764

High-Band Your KDK

-- monitor the other half!

It sounds almost blasphemous to talk about modifying a beautiful, synthesized rig, doesn't it? Well, it can be done, and it can be done by anyone who knows how to solder two pieces of wire. That's the whole modification. I can add two pieces of wire to the KDK and double its versatility.

Why To

The KDK, as it was designed, covers 144 to 148.995 MHz, and the receiver sensitivity leaves nothing to be desired, with the front end being tuned along with the synthesizer. The frequency coverage is so close to the public service band that it would be nice to have such a sensitive receiver, with a nice sharp i-f and precise frequency readout, to see how the other half lives. No sooner said than attempted.

How To

1. Take the cover off the rig (the two nuts on the back).
2. Lay it upside down with the front panel facing you.
3. Move the red wire on the on-off switch over to the terminal that already has the two white wires with violet tracers.
4. Solder a 1/2-inch piece of bare wire to the rear terminal of the other side of this same switch (the three terminals closest to you).
5. Find the top terminals of the aircraft-type frequency selector switch that have a jumper going from the front wafer to the rear wafer.
6. Solder a 6-inch piece of wire to this point (the rear wafer makes a neater job).
7. Solder the other end of this wire to the center terminal of the top bank of the on-off switch (see Fig. 1).
8. Find the frequency selector terminals on the shielded enclosure directly behind the front panel controls. The terminal you want is the one to the far right as you look at the rig. It has 2 white-with-red tracer wires connected to it.
9. Solder the wire from step 4 to this terminal (the one in step 8). Be very careful that some strands of the wires do not short to ground. I have done this many times, and this is not conducive to receiving.

How To Use It

With the on-off switch turned on, the rig works the same as it always did (if not, see step 9). With the switch off, the rig will stay on. It's very easy to add an external power switch, and I didn't want to drill any holes in the rig. However, you will see some very strange-looking megacycles on the readout. This is because you are feeding values in excess of 9 to the seven-segment decoder. It doesn't hurt anything, just makes it hard to read. If you add 8 to the frequency shown on the MHz switch, you will have the frequency that the rig is really receiving. The KDK now tunes 152 to 155 MHz. With the switch on 148 MHz, the modification doesn't do anything, and the rig still receives (and transmits) 148 MHz. It is possible, with additional switching, to extend the range from 140 to 155 MHz, inclusive, but what do you want for 2¢ and five minutes?

Possible Problem (Only One)

You may find that, when the rig is switched to 152 to 155 MHz, the unlock indicator does not go out (some do, some don't). This is due to the fact that the vco is just out of range. Adjust the vco tuning capacitor *very slightly* and *very slowly*, and you will find a point very near where it was that causes the unlock light to go out. If you are receiving a signal, again tune the vco capacitor for maximum S-meter reading on the signal.

The receiver, when properly tuned up, shows .2 uV sensitivity for 20 dB quieting on 2 meters and about .3 uV on high band. Not bad!

Theory

The terminals on the front of the shielded enclosure determine the division ratio of three 74192s. If the first one (the one on the right, looking at the rig from the bottom) divides by 4, we are on 144 MHz. If it divides by 8, we are on 148 MHz. (Aha! It determines the third digit in the megahertz number.) We simply placed +5 volts on the 8 terminal, so we added 8 to that number. On 148 MHz, there is already +5 volts on that terminal, so . . .

Enough theory, already. Try it; you'll have fun! ■

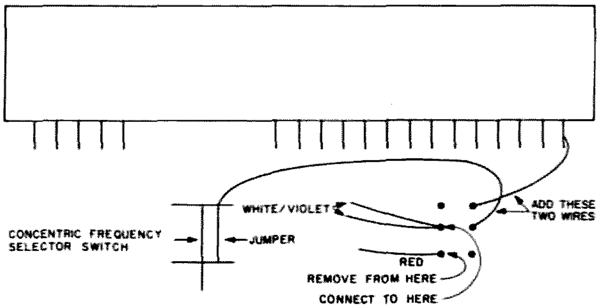

Fig. 1. How simple it is.

The Rescue

-- real-life drama

The temperature was about 82°, a perfect-day for exploring the back country of Fish Creek. Now, if you're not familiar with the whereabouts of Fish Creek, it's about 50 miles east of Jackson Hole, Wyoming, about one mile from the Continental Divide.

On this beautiful August 21, 1976, two young girls and a male friend decided to take the horses out for a ride in the back country. Nancy, 17, Patty, 19, and John, 17, saddled up the horses that they had been assigned to and started out on what was supposed to be a beautiful afternoon ride.

When you run a ranch, there is always much to do, so I set out with my two cowboys to do some of the chores that had been waiting to be done for some time. Now I think I should mention that the ranch is one and a half hours by four-wheel drive from the nearest telephone. A person could set out from the ranch in any direction and never see another living person for 30 miles. The only electricity is a small, four-cylinder engine generator. Many have said it is one of few ranches left that reflect the way the old west was in the early 1900s.

About 4:30 pm, while I was working in the pasture, I looked down the path to the east and saw a rider heading for the ranch at a full run. One of the rules of the ranch is to never run your horse, so I immediately knew that there was trouble.

In a few minutes, Patty rode up to where I was working. In a state of shock, she started screaming that Nancy was seriously hurt. After quieting Patty down, I got a description of where Nancy was and jumped into the four-wheel drive truck with Mike, another guest at the ranch. We headed for the canyon where Nancy and John were. The road was no more than a cow path, so the traveling was slow and bumpy. Once at the canyon, called Deer Creek, Mike and I started a one-mile hike looking for the injured girl and John. After about twenty minutes of rough hiking, we came upon them in a little clearing.

Nancy was lying on the grass in a state of shock, with blood flowing from her mouth. There was a lump on her head where she had hit the ground, and her left elbow was completely distorted. It was decided that Nancy could not be moved.

Grabbing one of the horses, I headed down the canyon as fast as the horse could go to where the truck was parked. I headed back to the ranch, where I hoped and prayed that the old generator would start. Once at the ranch, I was able to get the generator going, and I headed for my new Atlas 210, which I had just purchased a month earlier. The antenna was a 20 meter dipole on the roof oriented in a northwest and southeast direction. I wasted no time in finding a clear frequency and started calling "Mayday, mayday, mayday; WA6LJL/7 near Jackson, Wyoming, calling mayday. Someone come in, please."

I called several times and got no response. I didn't know what to do, as a girl was lying seriously injured, and this was the only means of help or communication with the outside world. I kept calling, and, then, like music to the ears, I heard "WA6LJL/7 this is K5TZK Bob in Houston, Texas. Do you copy?" Thank God someone heard me! It didn't take long for me to tell Bob the problem. Shortly after I made contact, Ernie W7JRW in Las Vegas and Jim WB5NRX were involved keeping the surrounding frequencies clear, so I could communicate with Bob K5TZK.

Bob immediately got the long-distance operator and explained the situation to her. She then connected the sheriff's department in Jackson, Wyoming, and the U.S. Forest Service Department with Bob in Houston. After about 15 minutes of my giving directions to Bob, the sheriff's department dispatched a helicopter and a registered nurse to our location. We were instructed to start some smoke fires so we could be spotted. For 30 minutes more I gave directions to Bob to relay to the sheriff's department, which in turn relayed them to the chopper.

As the drama continued, there was not a bit of QRM on the frequency, thanks to Jim, Ernie, and, I am sure, others, who helped keep the frequency clear.

It seemed like hours before I heard the low hum of the helicopter as it started to come into view over the

mountains. Seeing our signal fires, it wasted no time getting to us and making a landing. I told the hams on the frequency that it was here, and, all of a sudden, there was a chorus of "Hoorays," making the prettiest QRM that I had ever heard. I signed quickly and headed for the chopper. I boarded, and we took off to the location of the injured girl.

About five minutes later, we spotted the trio and made an unbelievable landing within 30' of where Nancy lay. By this time, she was unconscious. The nurse said she looked bad, so we wasted no time getting her on a stretcher and airborne. We all gave a sigh of relief as the helicopter headed for the hospital.

The next day I drove into town to the hospital to find out how Nancy was. I found her doctor and asked him how she was doing. "Doing well," he replied, "but if she had gotten here 2 hours later, we would have had to amputate her left arm, as the circulation had been cut off and the tissue was dying." Had we tried to take Nancy out by truck, it would have taken us 4 hours to get her to the hospital.

Today, many months later, Nancy is a beautiful young girl living in Palos Verdes, owing her life and healthiness to the many hams who helped. Without this help, she might not be alive today.

So let everyone know that there is no greater service fraternity anywhere in the world today than the hams, who would rather be of service to their fellow man than anything else.

Oh yes, I'll be back there again, and, again, I'll have my trusty little Atlas 210 with me! So, if you hear "WA6 Lovely Japanese Ladies portable 7," give a call and be sure to say hello, as you're the only commmunication we have with society. ■

Welding Rod Special Antenna

-- for seamless contacts

Most two meter mobile antennas manufactured today are easily mistaken for Citizens Band antennas, especially by CBers and, more importantly, a faction which, of late, has greatly proliferated — the CB rip-off artists.

Many articles have appeared concerning the use of burglar alarms and other devices to protect your rig, but few solutions have been offered concerning the most vulnerable part of your mobile system — the antenna.

The solutions seem to boil down to two things:

1. Take your antenna off when not using it, which is a hassle, even if you use a magnetic mount.
2. Let them take the antenna.

The second solution can be a viable one, providing the antenna is cheap, easily replaced, and doesn't look so great, so not many people bother to steal it anyway.

The antenna described here will adapt readily to the popular Antenna Specialists 5/8 wave roof or trunk mounts, as well as many CB mounts. If you don't have one of these, the roof or trunk mount, less antenna, can be purchased at your local Radio Shack (roof mount — part no. 21-914; trunk mount — part no. 21-913).

The antenna itself is easy to construct. The only materials required are a PL-259 coax connector and a 20-inch piece of welding rod, coat hanger, large copper weld wire, or what have you, and some silicone rubber sealant. Use a hacksaw or a large pair of diagonal pliers to cut about half of the pin off of the PL-259. Take the 20-inch piece of rod, clean the end, and solder it to the center conductor of the PL-259, trying to get a smooth, round bead of solder on the tip of the PL-259 to make good connection with the mount. Fill in the back of the plug with the silicone sealer, in order to keep moisture out.

The PL-259 sleeve is brought down over the rod and screwed over the connector in the usual fashion. The entire assembly may now be screwed down securely on the antenna mount. A 20" piece of rod is used, to allow for about 19" measured from the back end of the connector to the end of the rod, which is a good ball park figure for two meters. An swr bridge may be used to prune the antenna, by careful snipping with wire cutters, but I've never even measured my swr and haven't had any problems.

The antenna has been used on my car for about 8 months and works quite well. No one has yet bothered to steal it, but, if they do, I haven't lost much. I still keep my 5/8 wave in the trunk in case I go out of town and want that "extra 3dB." ■

Tanks A Lot!

-- inductor calculation program

If you don't own a programmable pocket calculator, chances are you will before too long. A 100-step programmable calculator is already on the market for less than a scientific-type pocket calculator cost two years ago. They're just too nice a toy to be overlooked by hams for long.

Now suppose you pull a variable capacitor out of the junk box and you want it to resonate with an inductor at a specified frequency. What's the value of L?

$$L_{uH} = \frac{10^{12}}{4\pi^2 (C_{pF})(f^2{}_{kHz})}$$

Not too bad. But now how do you wind the inductor to get this value of inductance? Well,

$$\text{turns} = \sqrt{\frac{L(9a + 10b)}{a^2}}$$

where a is the inductor radius and b is the inductor length. Now this gets a little messy. Squaring, dividing, and taking square roots is not a whole lot of fun. But there is another problem. Assuming we settle upon a value for the inductor radius, we still have to contend with the proper value for the length. How do we find b? Well, we know that turns per inch (tpi) times length equals turns. So if we vary the length b, carry out the above calculation to get turns, then multiply that same length by tpi and compare the result with turns, we can see how close we are. We want the difference between the two to be zero. So we change b just a bit and do the whole thing again and again until the difference is zero or very near zero. But that's a lot of work! You bet, but it's not for a computer.

The program shown here carries out the above procedure starting b at .05 and incrementing it by .05 units after each calculation and comparison until the difference between tpi times length and turns changes sign, that is, crosses zero. Then it decrements b by .001 units and continues in the same fashion until the sign changes again, whereupon it stops and displays the number of turns. The result is, for all practical purposes, excellent. One must initiate the program by putting the various parameters in the memory registers, all ten of which are used with my SR-56.

As an added feature, I thought it would be interesting to know how many times the subroutine

was called upon to carry out the searching calculation. In one problem that I devised, over 700 passes were undertaken. This bit of information is stored in register zero.

So how do you run it? Select your variable capacitor and, for example, its center position capacitance. Store this value in pF in file 2. Store the frequency in kilohertz in file 1, the number of turns/inch or less, from the closewound value in the wire tables, in file 3, and the radius you've selected in file 4. You can't have more turns/inch than the closewound value. Square the radius and store in file 7. Finally square pi and multiply by 4 and store in file 9. Now you're ready. Punch R/S. The calculator will display the inductance in microhenrys needed to resonate with pF at the specified frequency in an instant. Punch R/S again, and the calculator will continue computing until it stops and displays the number of turns you need to wind at your selected tpi and radius. Any of the memory registers can now be recalled. The computed length can be recalled from file 6. This length times tpi should be very close to the computed turns. Punch reset, and the program is ready to begin again.

Ah, you say, I can get the same stuff from the ARRL Lightning Calculator. True, but you can't get any information on an inductor 3 feet or 0.1 inch in diameter, and it doesn't have all those flashing lights. ■

Build the El Sapo Tester

-- for hams with spare time

73 Magazine *Staff*

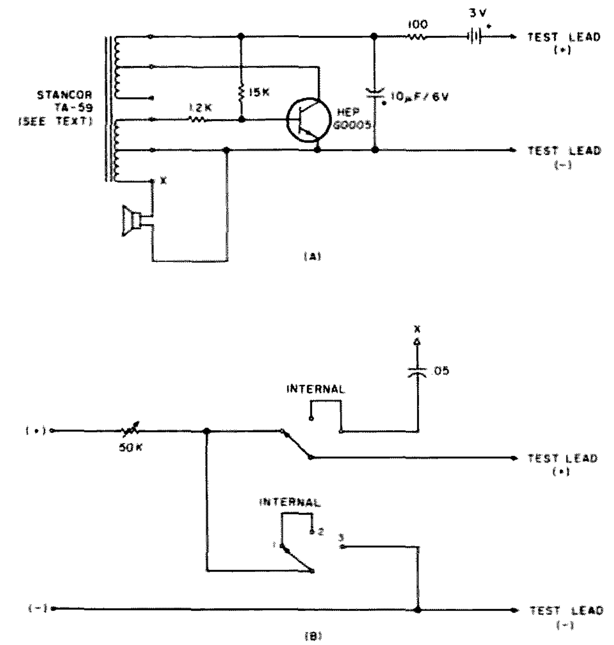

Fig. 1. Basic circuit of tester (a) and switching add-on for more versatility (b). See text for description of components not marked.

The little test instrument described in this article is something for the amateur who has nothing and something for the amateur who has everything. In the former case, it provides, very inexpensively, an instrument that can function as a continuity tester, transistor tester, diode tester, signal injection source, code practice oscillator, CW monitor, substitution microphone, and substitution loudspeaker. In the latter case, it provides a very handy addition to a tool box, for quick continuity and relative resistance checks, without having to look at a meter.

The instrument is nothing more than an audio oscillator using a one transistor circuit. But the components are carefully chosen. A switching scheme is utilized so that a low current is passed through the circuit under test. The volume and/or pitch varies with the resistance placed across its test terminals, and maximum utilization is made of the circuit and its components for several modes of operation. Such basic testers, but without all the versatility of the one described, have been available commercially for years. They are popular with many service technicians, since one can visually concentrate on the circuit being tested or traced out without having to glance away to read a meter. This feature is particularly helpful when doing work on a detailed PC board, since one can lose one's place on the board in the time it takes to glance at a meter.

The circuit of the unit is shown in Fig. 1(a). The oscillator circuit utilizes a transistor transformer, which has one or two center-tapped windings to form the equivalent of a transformer with three windings. One winding is used in the base circuit of the transistor, another as a feedback winding in the collector circuit, and another as an output-coupling winding. Many of the usual miniature transistor transformers will work, aside from the TA-59 unit mentioned, such as the usual 10k Ohm to 2k Ohm CT or 1k Ohm CT to 8 Ohm units. One must be prepared to do a bit of experimenting to get the windings phased correctly and to get the output pitch desired. To achieve the latter with some transformers, it may be necessary to experiment with a small capacitor (.001 to .1 mF) across the base winding. The output "loudspeaker" should ideally be a unit such as a 600 Ohm telephone receiver. But anything, from high impedance, miniature loudspeakers to cheap, dynamic-type

microphones, can be used. Power is supplied by two 1½ volt batteries in series. No on/off switch is required, since no current can flow unless some resistance is placed across the test terminals.

The unit, as shown in Fig. 1(a), can be used by itself, if desired. If the test leads are marked for polarity, one can test diodes and transistors and determine the direction of the junction involved. Resistance values, from a short to about 100k Ohms, can be detected with the upper limit, depending on the specific oscillator components used. As the resistance value increases, the volume will decrease, but the pitch will tend to rise. This is a very handy feature, since, after a period of usage, one is not so aware of the volume changes as one is aware of associating higher pitch with higher resistance. With usage, one can become familiar with the sound of at least the major steps in the output pitch, such as for resistance values of 1k and 50k.

By adding a few more components to the basic circuit, as shown in Fig. 1(b), more versatility can be gained from the unit. The addition of a series 50k potentiometer allows one to control the volume and also to limit the short circuit output current to less than 60 uA. The latter is useful as a safety feature, when testing some semiconductor devices, when one is unsure of the terminal markings. In the center position of the switch shown, the battery line is left floating, and the positive test lead is connected to the speaker over a .05 mF capacitor. The speaker can then function as a replacement test speaker or as a dynamic microphone replacement. The reproduction quality is good enough to at least determine whether or not the speaker or microphone substituted for is basically defective. In the right-hand position of the switch, the battery circuit is completed to ground, and the internal speaker output remains connected to the positive test lead. In this mode, the circuit functions as an injection oscillator, the level of which can be controlled by the 50k potentiometer and monitored on the internal speaker. The output is quite harmonically rich, and it can be used to check amplifiers all the way from the audio range to the HF range.

The switch used in the unit I constructed was a special miniature DPDT toggle switch with a center position. But, in the center position, instead of the usual "off" position, the poles still remain connected to opposite side terminals of the switch. The switch is available for $1 from Tri-Tek, 6522 North 43rd Ave., Glendale AZ 85301. The switch can, of course, be replaced by a regular 2P3T rotary switch, but, then, this requires a larger enclosure. Using the miniature toggle, and with the basic circuit wired on perfboard, the unit was assembled in a 3-1/4 x 2-1/8 x 1-5/8 Bakelite box, complete with batteries.

Probably some more uses can be found for the circuit, with a bit of imagination and a modified switching scheme. For instance, it would seem possible to rearrange things so that the circuit could also function as either a preamplifier or a low level audio amplifier complete with speaker. All in all, it is hard to find a more handy unit for general circuit or equipment checking, before one resorts to proper instruments for specific checks.

The name of the instrument comes from the sound the unit makes. When you test for continuity and encounter a very low resistance, the unit sounds off with a hoarse tone, sounding somewhat like that produced by El Sapo – the frog. ■

Finally!

A Simple PROM Burner!

-- for the 8223 and 82S23

William J. Hosking W7JSW
8626 E. Clarendon
Scottsdale AZ 85251

As a result of my various articles using TTL programmable read only memories, I have received many letters and phone calls for help from people who cannot get devices they have purchased to accept a program. In almost all cases I discovered that they had been sent 82S23s, assuming that 82S23s were the same as 8223s. While the devices do the same job with the same pin connections, they are quite different when it comes to programming. The 82S23 will not program with the same inputs as an 8223.

After doing some research into the device data books and getting some help from a friend, the following circuit was developed which will program either the 8223 or the 82S23.

Circuit

The circuit is shown in Fig. 1. To those of you who have either read my earlier articles or used the Signetics data book, the circuit should appear quite familiar except for the additional power supply input and the FET-zener circuitry.

It turns out that the 82S23 requires 19 volts current regulated to about 65 milliamps in order to program right. The circuit shown in Fig. 2 will perform that quite nicely. The only limitation is in the selection of JFETs. The JFET must have an IDSS of greater than 65 mA. Of course the 19 volt zener must be able to handle the full 65 mA, which means that it should be rated at least 5 Watts.

The remainder of the circuit in Fig. 1 is fairly straightforward. For S1 and S2, I used thumbwheel switches which select the word address in octal. These could be replaced with cheap toggle switches, but the saving in time and effort is well worth the slight extra cost of the BCD coded thumbwheel switches. S3 selects the output bit to be programmed or verified. S4 is a push-button switch used to do the programming once a word and bit are selected, and S5 is used to verify that the bit was actually programmed. S6 was added to switch the programmer from the 8223 devices to the 82S23 devices. S7 simply puts a 12 volt zener across the 19 volt zener for current calibration purposes. The 21 to 19 volt supply is the same as shown in detail in Fig. 2 except for the addition of a meter for current calibration. For the best stability, the zener and FET should be mounted on heat sinks. One last circuit

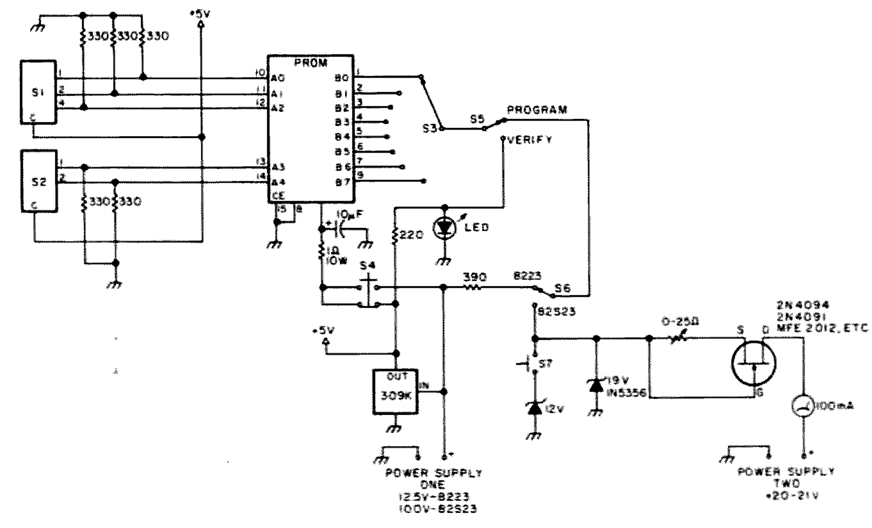

Fig. 1. PROM programmer schematic diagram. Power supplies one and two can be bench supplies or built up specially for this use. Regulation is not critical.

comment: If additional contacts were available on push-button switch S4, I would break the line from S6 to S5 and put it through the extra contacts.

Programming

If programming an 8223, set S6 to 8223 position and adjust power supply one for 12.5 volts. Power supply two need not be on.

If programming an 82S23, set S6 to 82S23. Adjust power supply one to 10.0 volts and power supply two to 21 volts. Now momentarily depress S7 and adjust Ra for a current of 65 ±3 mA. Turn power supply one off, insert device to be programmed, and set S1, S2 to desired octal address. At each address select, one by one, the bits to be programmed with S3. Then momentarily push S4. Now, pushing S5 to the verify position should cause the LED to light if the programming was successful. When all desired bits of one word have been programmed, switch S1, S2 to the next address and repeat the operation.

Conclusion

I have two words of warning for programming either type of device. Monitor the device case temperature with your finger. Any time you can't keep your finger on the device it is time to stop for a few moments to let the device cool down. The other warning is that, once programmed, a TTL PROM is forever programmed whether right or wrong, so it takes time and care to do the job right without destroying a device. I hope this article will help those of you who have had problems or been frustrated by these devices. ■

Try A Topical CQ

-- for special interest groups

When I became interested in personal computers, I developed an intense desire to talk to someone — anyone — who shared my enthusiasm for this new and fascinating hobby.

Don't let the term "computer" turn you off. This article is about amateur radio, not about computers. Bear with me for a few moments, and you'll see. I mentioned my interest in discussing computers as a prelude to disclosing a practical solution to the problem of locating someone who shares your interests, whatever they may be.

Since my home town is comfortably small, I wasn't too surprised to discover that I was the only one here who was active in tinkering with a personal computer system. Therefore, when I had questions about computer hardware or computer programming (and believe me, I had many), I became frustrated. I had no one to whom I could turn for enlightenment.

One day, as I was sitting at my bench busily creating an ulcer because I couldn't understand the instructions that some engineer had prepared to help me, I chanced to glance over at my rig. It had been neglected, shamefully, since I had become interested in computers.

Suddenly the thought struck me — surely, someone out there in the ham radio community knows how to interpret this jargon that I've been trying, unsuccessfully, to understand. As I turned on the rig and began tuning it up on 20 meters, I gave no conscious thought to the means I'd use to reach someone who might answer my questions.

"CQ computers, CQ computers," I called into the mike. "Calling anyone who can help me interpret some microcomputer buzzwords." The plea came out as naturally as if I had used the special topic CQ all of my (considerable) amateur radio life.

I wish I could report that an electronics and computer programming expert who had built and operated the exact make and model of my computer had responded. No such luck. But I did get calls from several fellows who were able to clarify the instructions that I had been misinterpreting.

In fact, three QSOs, which lasted several hours, resulted from that topical CQ. I had an opportunity to discuss and learn a great deal about hobby computers that day. It's a gross understatement to report that I enjoyed that experience immensely.

The frustration that drove me to call "CQ computers" may have had a significance for the enjoyment of amateur radio that I never before considered.

What's wrong with calling a topical CQ? Why not call "CQ color photography," "CQ Windom antennas," "CQ linears," "CQ bass fishing," or "CQ recreational vehicles"?

I realize that such CQs sound strange. But perhaps that's just because we haven't heard topical CQs before.

We are all familiar with "CQ DX," "CQ New York for a phone patch," "CQ contest," "CQ for a test," and "CQ for a short QSO." Those calls certainly don't sound strange anymore.

The beauty of the topical CQ lies in its promise of bringing together two (or more) hams for the sole purpose of discussing an announced topic in which both (all) are interested.

The rag chews that used to take place on 75 phone just after World War II were fascinating, in part, because they involved discussions of transmitter, receiver, test equipment, and antenna projects that were in various stages of construction. Most ham gear was of the home brew variety, and almost everyone was engaged in a building project he wanted to discuss. That commonality of interest was what contributed most to the satisfaction one gained from a QSO. If you doubt it, ask a ham who owns a two-letter callsign how often he stayed up until three or four in the morning chewing over construction projects he enjoyed discussing with others.

It's the search for that elusive common interest topic that occupies most of our time at church socials, PTA meetings, cocktail parties, bus stops, or most other gatherings. What we refer to as "small talk" is really this exploratory probing for a subject that interests us. Often, we start with the weather. Then we switch to the old home town, mutual friends, television, children,

traffic problems, disasters, politics, etc., to keep the conversation going while we continue our search for a common interest.

Then, without warning, we pick up a chance remark that leads to the exciting moment when we discover that someone else shares our interest in something. From that moment on, our conversation comes alive, as we share our views and experiences with someone who seems to hang on our every word. A topic of mutual interest has been discovered. The evening is a success; a new friend has been found.

A similar phenomenon occurs repeatedly on the amateur radio bands. In fact, many hams resign themselves to the expectation of a casual conversation. You hear them call "CQ for a short QSO," meaning: "Let's get together to exchange handles, signal reports, QTHs, weather reports, and descriptions of our rigs."

Fortunately, on occasion the "short QSO" can stretch into hours, if some remark made discloses that both hams have a common interest in some topic.

Back to the topical CQ.

As I see it, calling a CQ that announces your interest in discussing a specific topic comes close to insuring that you and one or more other hams are likely to have an enjoyable QSO, QRM permitting. There's no guarantee of a stimulating exchange, of course, because the expertise of all participants as well as the level of interest in the topic by participants play a significant part. But the topical call certainly holds far more promise of satisfaction than does the general CQ with which we are all familiar.

As an added incentive to use the topical CQ, think of the prospect of some ham having a rare DX call responding to your call because he is tired of hit-and-run QSOs and is anxious to discuss your favorite subject with you. It could happen.

There is no good reason why the topical CQ couldn't be extended to seeking help with some project in which you've become involved. My initial call was a plea for help in understanding computer terms, despite the fact that I was thinking of the call at the time as merely an attempt to discuss computers. There is no doubt in my mind now that I was looking for someone who might add to my limited fund of knowledge, i.e., someone to help me.

Over the years, I have listened in on QSOs during which hams have instructed one another on how to tune an antenna, adjust a discriminator circuit, rebuild a VW carburetor, remove the flywheel from a lawn mower engine, prime a water pump, repair a sailboat centerboard, and locate a locksmith on a Sunday afternoon. I have even heard a physician offering medical advice to one of his longtime net buddies, but that's carrying too far the help requests I'm advocating here.

Hams, generally speaking, are people who are unusually alert and have wide diversities of interests and talents. Few will deny that hams are responsive to one another's calls for assistance. Each of us has knowledge and experience that we are willing to share, if only we are made aware of the need.

A topical CQ can announce that need for assistance or can merely signal a desire to contact someone for the purpose of exchanging views about a subject that is of special interest to the person initiating the call.

So, how about it? If you want to talk about my current special interest, personal computers, I'll be listening on 20 meters for your topical "CQ computers" call. ■

Call Letter Gouger

-- adds class to any shack

High school wood shop instructors are always looking for simple, educational, inexpensive projects for those students who need to be kept busy until such time that they come up with their own projects.

Keep in mind that this project must have educational value for the instructor to justify putting a student on it, and the process of education is a slow one. You will actually be doing the instructor a favor with your request, since he is always looking for just this kind of project. Shown is a piece of cedar, stained first, then routed in about 20 minutes by one of my students while he was waiting for his own project to dry before applying the next coat of sanding sealer. I'm sure WB6TJV will be pleased with the results. ■

RECIPE

Take accompanying photo to local high school wood shop instructor.
Supply him with your call letters.
Furnish $1.00 to $1.50 in U.S. funds.
Wait suitable time for educational process.
Completed callsign will be returned so you can hang it out front of the shack.

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

from page 41

for the most part gotten into HFing.

The move by the ARRL to force dealers to sell ham gear only to hams by refusing to let them advertise in *QST* if they don't promise to be good is about what I would expect from the ARRL. There is something about the bureaucratic temperament which seems to always think in terms of punishment as a way to force people to do their bidding rather than using rewards for behavior mod. Their forcing the FCC into "incentive licensing" was typical . . . forcing hams to get a higher license by taking away bands unless they did. The bureaucratic system of making ever more laws to force people to do what the bureaucrats think is right has not been noticeably successful.

A handful of ham dealers have been making a killing for several years by selling ham rigs to CB dealers for resale to HFers. All they have to do is change a wire or two, add a couple of crystals, tune it up, and move it along for a very nice profit. The dealers, such as Tufts Electronics, which refuse to sell ham rigs to CB dealers or directly to CBers, are at a disadvantage. This loss of sales volume can mean higher prices for some equipment and slower delivery.

Traffic in ham rigs to HFers will slow down when it becomes unprofitable for the ham dealer to indulge in it. There are ham dealers out there who will sell to anyone waving money and even sue the manufacturers if they refuse to ship to them for this trade. While the entire industry looks with disgust on these "sewers," they still have to do business with them or else spend a lot of money on lawyers, with the courts eventually backing up the sewers.

Other than making ham gear in short supply for hams, what problems are HFers causing us? Oddly enough, not all that many. The added volume of sales they represent helps keep ham rig prices down and encourages the development of new equipment. The amplifiers the HFers buy are generally the higher-powered ham amplifiers and thus are relatively free from spurious emissions. Even the FCC admits that the HFers aren't seriously bothering any other service. Perhaps this explains why, though the FCC people at HQ in Washington are bent out of shape over HF operation, little is being done in the field to discourage it . . . even when ham groups get together and supply detailed information about HFer names, locations, equipment, etc.

Will an edict from the ARRL/*QST* change the ways of business when the FCC doesn't seem to really care and when the people involved are not causing any serious damage? It seems unlikely to me that this is anything more than a grandstand play. We'll see.

Ham dealers who sell gear to CBers are quite aware of what they are doing. Chuck Martin WA1KPS of Tufts Electronics comments on the ARRL demand that customers show a ham license to buy a rig, "Are you kidding? We can tell a CBer the minute he walks into the store. We don't waste time asking for ham licenses . . . it's too easy for anyone to borrow one for a purchase. One or two questions and we know who is a ham and who isn't. We sell ham rigs *only* to hams."

The FCC is terribly upset over the TVI and other interference complaints caused by the many illegal power amplifiers being sold to add on to the 4 Watt AM rigs. Since the FCC put the ethical manufacturers out of the business, they've opened the floodgates for the unethical manufacturers . . . who have no reason at all to worry about spurious responses. The result has been hundreds of thousands of incredibly dirty power amplifiers being sold and a resulting tremendous increase in interference.

The manufacturers of legal ham amplifiers have been trying to point out to the FCC that a further restriction on making clean amplifiers will obviously result in the production and sale of dirty amplifiers. Laws further prohibiting amplifiers will result in exactly the opposite desired end. There has been no sign of anyone listening at the FCC. I do think that further prohibitions of linear amplifiers would be about the worst thing the FCC could do. They'll probably do it.

COMPUTERIZED QSLS?

The RTTY chaps have been sending their QSLs by radio for many years; however, I doubt if these confirmations are considered adequate by the organizations issuing certificates.

With more and more microcomputers in the hands of hobbyists, it is probably just a matter of days before a system will be devised to allow the access of one computer by another via the telephone system for either leaving a message or picking one up. Indeed, I'd like to publish the details on the interface boards for accomplishing this, complete with details of the standards and protocols developed to accomplish a confirmed automatic message transfer.

With the phone rates going as low as 19¢ per minute at some hours, this offers a reasonable and fast system as an alternate to the U.S. mails. Even the daytime 40¢ per minute charges aren't bad for a priority message, delivered within a minute or so instead of having to wait until night.

In the past, some organizations have been very sticky about accepting QSL cards which have neither a canceled postage stamp on them nor the stamp of a QSL bureau. I can understand the situation, for one of the early aspirants for one of the *73 Magazine* operating awards sent in some QSL cards which looked perfectly okay, but were fakes. They lacked the QSL bureau stamp or postage to indicate mailing. Fortunately, the fakes included cards from some rare DX stations which I had worked, and I quickly recognized the bogus cards submitted. Tsk.

As more operators use microcomputers, we may be able to have cassette tapes of the logs submitted by DX stations and do away with QSL cards. In the meanwhile, put on your thinking cap and see if you can come up with an interim solution.

The high (and going higher) postage plus slow (and getting slower) deliveries of our postal system are going to help encourage the use of computer-to-computer messages. The Postal Service has its own problems, and it is going to be a long time before they will be permitted to tackle most of the more serious ones . . . so there is no immediate hope of lower postage or much better service.

One of the big miseries of the Postal Service is the political constraints. There are over 12,000 post offices in small towns which could be closed, saving over $100 million annually. These are kept open as a matter of town prestige, not of function. Another big lump could be saved if more rural mail could be delivered to clumps of post boxes instead of free delivery to each customer at his home. When I was young, our post box was almost a half mile away, and I didn't think anything of walking down to it . . . at least not on warm days. Of course, our farm was out a ways . . . we didn't even have electricity (it still doesn't) . . . or running water (still doesn't).

When the Postal Service is permitted to be run more like a business and less like an arm of the government, I think we'll get better and cheaper service. In the meanwhile, the pressure for faster and cheaper service may quickly force the development of computer communications. As pioneers in communications, perhaps hams will be in there with the first systems and help develop the standards which will stick with us.

CATCH 22 FOR HAMS

Early experimenters with RTTY found that they were severely limited in their possibilities by the FCC. Even though the amateur service is chartered by the FCC rules to provide inventions and pioneering, the FCC has constantly gone counter to their regulations by prohibiting any experimentation which would produce signals which the FCC monitors could not copy. So how are hams going to invent something new if anything new is prohibited? Catch 22.

One of the questions I've asked at FCC formal and informal hearings is why . . . why . . . the FCC monitors have to be able to copy ham transmissions using new techniques? If what is being transmitted is so difficult to copy that even the FCC monitoring stations can't hack it, what do they care about what is being transmitted?

Perhaps there was, long ago, the fear that hams would go berserk and send naughty words over the air if they thought the FCC monitors couldn't copy them. Well, I've a secret . . . this is probably one of the first things hams will do. So what? That gets boring very quickly and the pioneers will be on to more interesting matters. There hasn't been any proof that words will do much long-range damage, so let the child in the ham come out and get over the excitement of being able to secretly pass naughty words. Big deal. The important thing is for ham experimenters to have the freedom to try new ideas, new types of communications, new techniques. And they should be able to give these things a try without a seven-year wait from the FCC for permission.

The current FCC ban on amateurs using ASCII is, unfortunately, well precedented by earlier refusals to allow amateurs to do other just as innocuous things. Here we are being held back for years, while the FCC blunders through its molasses-slow procedures to permit what should have been automatically permitted at first request.

FCC HEADACHES

The FCC Amateur Division made the papers recently over the call letter business where one of the FCC employees was accepting cash in return for choice calls. I wish I'd heard before it got stopped.

For years I've been interested in getting W1NSD, but the FCC has put me off, saying they couldn't do it. The call has been open for about 25 years. At one time, I even put in a petition to make it possible to get counterpart calls such as this. The League liked the idea, too, and they also put in a petition asking for the same thing. These petitions, after yellowing for about eight years in the FCC files, were recently thrown out, with no reasonable explanation.

It was my own fault. I could have gotten the call if I had not goofed off. When I moved down south, I was able to get W4NSD. Later, when I moved to Ohio, I got W8NSD. That was back in the '40s and '50s. As a matter of fact, in the Sweepstakes contest of 1951, if you have an old issue of *QST* around, you'll find that I operated the first weekend of the contest as W2NSD/8 (and did quite well). The second weekend of the contest I ran as W8NSD/2 (my new call had arrived just as I was going to New York for a few days).

By 1962, when I moved to New Hampshire, the FCC had stopped giving counterpart calls. There was no rule change; they just decided not to do it any more . . . too much trouble. Having lived in New Hampshire off

Adjustable Bench Supply

-- would you believe 1.2-37 volts?

How about constructing an adjustable voltage power supply that can have up to 1.5 Amperes output with good load voltage regulation and full overload protection at minimal cost? Admittedly, a $5.00 estimate depends a lot on what parts are available from one's junk box, but for just a few dollars spent on a new IC, one can have the "heart" of a very versatile power supply.

The new IC is the LM317 by National Semiconductor. This IC promises to be as famous as the LM309, which is so universally used in power supplies for digital circuitry.

The new LM317 is an adjustable, three-terminal positive voltage regulator. Its simple external connections rather belie the complexity and performance features of the unit. As shown in Fig. 1, it has only simple in/out connections and a minimum of three simple external components are required. The output voltage is set by the ratio of two resistors, R1 and R2. By making R2 variable, one can adjust the output voltage to be any value from a few volts less than the dc input voltage to the regulator down to a minimum of about 1.2 volts output. Thus, if the input dc voltage were 40 volts, the output voltage can be continuously varied from about 37 volts down to 1.2 volts.

Although the output voltage is determined only by a resistor setting, the output voltage is regulated at *any* given setting. The regulation will be about 0.1% going from no load to full load (1.5 Amperes, assuming the transformer/rectifier used for the dc input voltage handles this current). The LM317 is also overload and thermally protected. If the current limit is exceeded, such as by a short circuit, the LM317 will simply "shut down." If the regulator gets too hot, either because of excessive load current and/or inadequate heat dissipation, it will also protect itself. Although one can destroy the LM317 like any other IC, it is pretty hard to do with any sort of reasonable care.

The manufacturer suggests two additional capacitors (C2 and C3) be used, which may prove useful in some applications. C2 is used to bypass the adjustment terminal to ground to improve ripple rejection. This bypass prevents ripple from being amplified as the output voltage is increased. About 60 dB ripple rejection is achieved without this capacitor, but it can be improved to about 80 dB by adding it. A 10 mF or greater unit can be used, but values over 10 mF do not offer any significant advantage in further ripple improvement. The manufacturer particularly recommends the use of a solid tantalum capacitor type since they have low impedance even at high frequencies. An alternative is the use of the more readily available and inexpensive aluminum electrolytic, but it takes about 25 mF of the latter type to equal 1 mF of the tantalum type for good high frequency bypassing! C3 is added to prevent instability when the output load presents a load capacitance of between 500 and 5000 pF. By using a 1 mF bypass at the output (solid tantalum again or aluminum electrolytic equivalent), any load capacitance in the 500 to 5000 pF range is swamped and stability is ensured. Both C2 and C3 will not be required for many applications where the LM317 is being used with a specific load circuit. But if the LM317 is used as the heart of a general purpose bench type power supply, they should be included.

Fig. 2 shows a PC board layout and component placement diagram. This layout has been suggested by the manufacturer, but there is no need to follow it exactly as

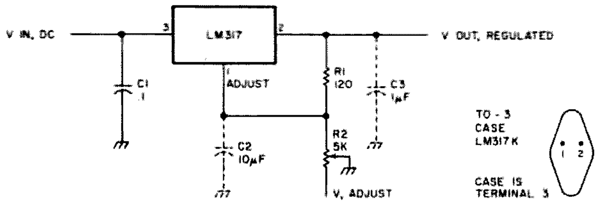

Fig. 1. Basic adjustable voltage regulator circuit using an LM317. Normally only three external components are needed, but C2 and C3 may be useful in certain situations as explained in the text.

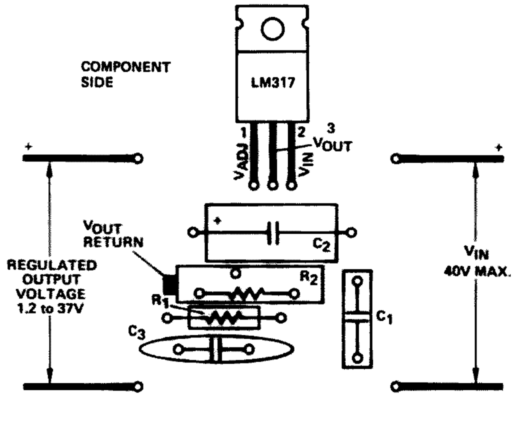

Fig. 2. This is a PC board layout for the regulator suggested by the manufacturer. R2 is shown as a multi-turn pot for ease of adjustment. The figure also shows the pin connections for an LM317 if it is obtained in the TO-220 plastic case.

long as all of the external components are grouped around the regulator with solid short leads. The diagram shows the LM317 in a TO-220 plastic case which is designated the LM317T. Most amateurs will probably prefer to buy the LM317 in the familiar TO-3 metal case and, in this case, it is the LM317K. But, when using the unit, note an important difference as compared to the old LM309K. The case on the LM309K was ground so one could simply bolt the thing down on a chassis for heat sinking. The case on the LM317K is the output terminal, so it must be properly insulated from a chassis.

Various power supply ideas and considerations can suggest themselves for the LM317. For instance, R2, instead of being a variable resistor, can be replaced by switchable fixed resistors to obtain some of the commonly used supply voltages such as 6, 9, 12, 15 volts, etc. This idea, plus a continuously variable output voltage position, is featured in the practical realization of a power supply using the LM317 as shown in Fig. 3. This supply will deliver fixed output voltages of 6, 9, 12, and 15 volts (depending upon how the trim potentiometers are set), plus a continuously variable output of 1.2 to about 24 volts. All outputs can deliver at least 1.5 Amperes with the components specified. The supply is simple to build in any size metal enclosure suitable for the components used. The only precautions to observe are to firmly heat sink the LM317 to one side of the metal enclosure and to keep the 0.1 mF capacitor going from pin 3 to ground, the 10 mF capacitor going from pin 1 to ground, and the 120 Ohm resistor going between pins 2 and 1, *all* connected directly at the LM317 terminals. The other components may be mounted wherever it it convenient to do so.

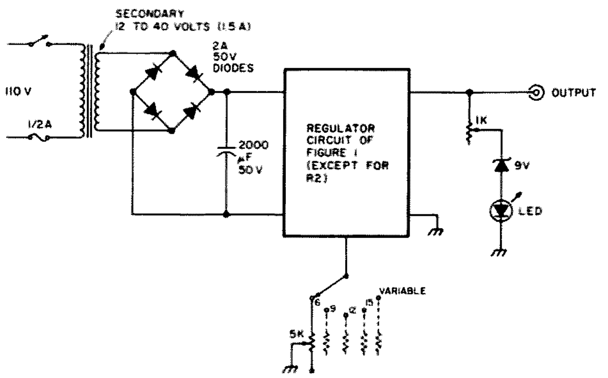

Fig. 3. A complete power supply using the LM317. The switch simply selects different 5k Ohm pots which are set for 6, 9, 12, 15, and a variable voltage output. The latter 5k pot is front panel mounted. The function of the LED is described in the text.

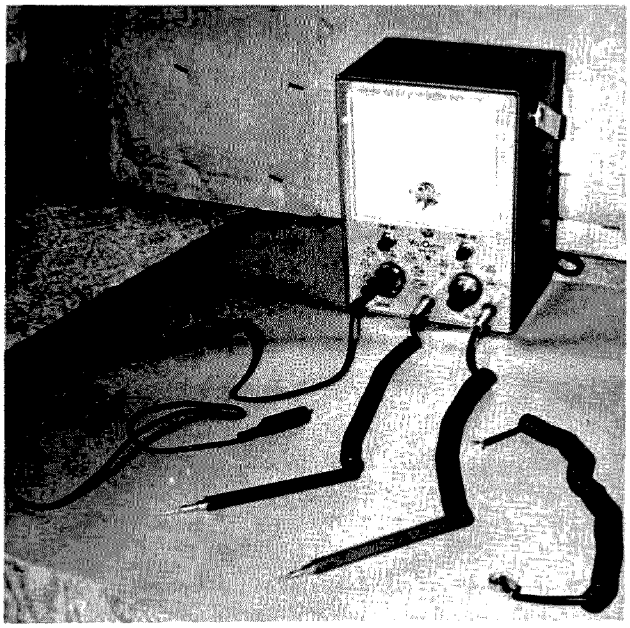
The zener diode/resistor/LED combination at the output of the supply serves as a crude but useful voltage output indicator without having to build a regular voltmeter in the supply. The LED just starts to glow when the output voltage is about 9-10 volts (depending on the tolerances of the components used). The 1k resistor is adjusted so the LED just glows fully when the *maximum* output voltage is reached. So by using the fixed output voltage positions (which are adjusted using a good VOM) and watching the LED, one can obtain a fairly good estimate of what the variable output voltage is set for. ■

Test Instrument Saver

-- an old phone is required

Harry J. Miller
991 42nd St.
Sarasota FL 33580



Delicate, costly test instruments may suffer severe damage when their conventional, too long leads snag on tools or on components spread out on the workbench and are inadvertently yanked off it to the floor.

A partial cure for this hazard is to replace the long leads with the much shorter coiled leads commonly used on cameras and flash units.

The coiled leads can be stretched out to where needed. When let go they retract out of harm's way. Should they lose their recoil power, rewinding the coils in the opposite direction helps restore their springiness.

Since each lead has two wires, their extra continuity gives them longer life. ■

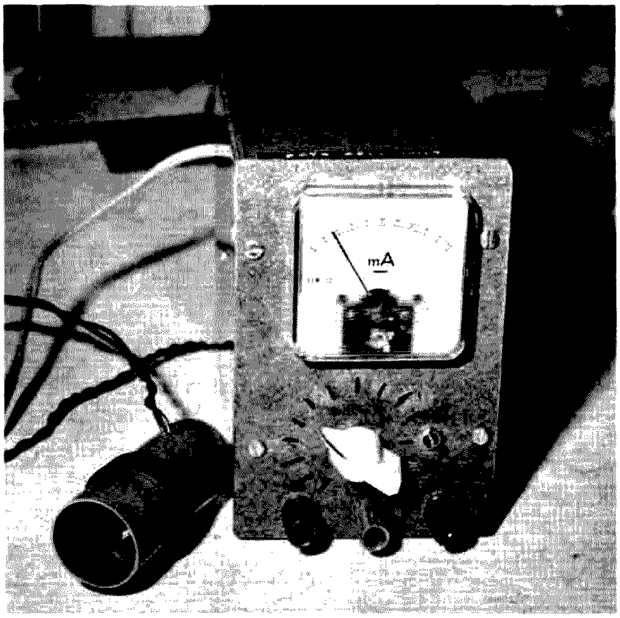
Photoelectric Bench Accessory

-- when you need an extra "eye"

Combine the leftover power supply from an experiment that failed with some twelve for a dollar CdS photocells purchased from S.D. Sales. Mix well with a lull in regular ham activities and the result is an interesting unit with many uses.

The diagram in Fig. 1 shows the basic unit. The photocell is in series with a pot. There is a voltage applied across this series combination to ground. The op amp is used as nothing more than a high impedance driver for the one mil meter used as an indicator of *relative* light flux impinging on the cell. The word "relative" is important to note, as the meter is not calibrated in any special units. Its reading is comparative only and its function is to tell you that light has either increased or decreased at any specific moment. The pot is used to control sensitivity. The higher the resistance, the greater the sensitivity of the unit. The photocell is mounted on two back to back lids from 35 mm film containers of the plastic variety. One film can makes up the body of the probe. This has a hole cut in the side to allow the cell leads to exit. Exiting the leads from the side rather than through the bottom allows the probe to be firmly positioned relative to a light source. A second container has its bottom cut off and is used for a stray light shield around the cell. These details are apparent in the photograph.



Notice that there are two outputs: One is dc coupled through an isolating resistor and the other is ac coupled through a 3.3 uF capacitor.

With the values indicated, here is an idea of sensitivity for general use. An LED energized from an audio oscillator and held next to the cell will give about ½ volt of audio at the exciting frequency when the unit is at maximum sensitivity. This makes a handy bench coupler into your counter. A sixty Watt bulb in a white glass shade will pin the meter from a distance of about nine feet as will an ordinary two cell flashlight.

If you play around with QRP rf levels and are addicted to using pilot lamps as power indicators for tune-up, this unit will allow you to convert the light into a meter reading that seems much more sensitive to slight changes than the eye. When you are fighting for each milliwatt, this is very helpful.

The unit puts out a nice dc pulse with a flash of light hitting the cell. Thus the dc output can be used for triggering an SCR or used to bias the base of a transistor used as a switch or some form

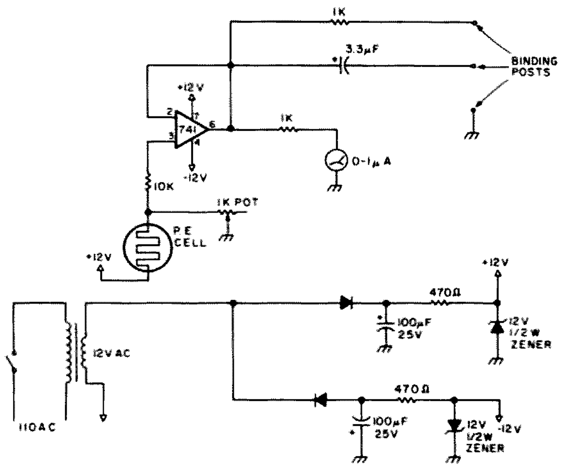


Fig. 1. All resistors ½ W.

of dc amplifier for control purposes.

If you wish to raise the overall sensitivity of the unit, merely increase the value of the pot to 5k or 10k. This will greatly raise the sensitivity but may create stray light problems. For general use, the indicated values work very well.

There is nothing magic about the voltages shown for the op amp; I used an existing supply, but six volts or so would work as well.

Note that there is no need to use shielded cable for the cell leads.

As with most projects, just about the time you get the last screw in place, there is that little voice whispering in your ear, saying, "I wonder what would happen if . . . ?" Well, this project was no exception. Fig. 2 shows what happens when you listen to little voices.

The ac power supply has disappeared, replaced by two C cells in series. The op amp has vanished because a more sensitive (50 microamp) meter has been used. The diode in series with the meter is used to provide a holdoff threshold effect so a small steady meter reading is cancelled. Either unit does about the same job of providing your bench with a photocell dimension that will find many uses. ■

Inside the SR-52

-- calculator doubles as micro

If you are anything like me, this business of math formulas as used in electronics today is enough to scare you half to death.

Being a basically lazy but inquisitive sort, the need for mathematical answers when designing some pet project kept rearing its ugly head. About a year and a half ago I broke down and bought my first scientific calculator, a Texas Instruments SR-50. I loved this instrument, and its ease of use made those formulas I had hated in the past child's play. But the SR-50 had a nagging problem which took some of the edge off the fun. Its problem, simply stated, was only one memory. This fact made me resort to the pencil more times than I cared. Something had to be done.

Then one day, something was done. The first programmable calculator with multiple memory came upon the market. I fell in love instantly and dreamed of the day when I, too, could carry the wisdom of Solomon in my back pocket. But the early introduction price of almost $400.00 made me hesitate. Wisdom was fine, but for $400.00 I found that I could push an awful lot of pencils.

Gradually, as time wore on, I watched the prices drop until one day it broke the magic $200.00 figure, and I rushed with sweatstained, crumpled bills to my local calculator emporium to buy my first programmable calculator ... no, not calculator but, rather, mini pocket computer ... the magnificent SR-52.

Oh joy of joys, oh thrill of thrills, for the next two days I sat mesmerized by the winking, blinking, flashing numbers. At last the drudgery of math was truly defeated.

The programmable pocket computer is a very powerful tool, and, whether you write your own programs or use those of someone else, it is a constant joy. For those of you who have recently bought your first instrument but have not mastered the knack of programming, here is a simple program to calculate Xc, capacitive reactance.

Simply stated, the formula for capacitive reactance says: Xc in Ohms is equal to the reciprocal of frequency in Hertz times capacitance in farads times the quantity 2 pi. What a drag to wade through that humbug. But with the accompanying formual keyed into your favorite SR-52 or SR-56, it suddenly all becomes child's play.

Turn on your machine, press LRN and up pops 000 00. The first three zeros indicate the step number, and the last two zeros indicate the key to be pressed in teaching the calculator its smarts. An extremely well written set of books comes with each and every machine, and in the back of the small book with the SR-52 is a chart detailing each key as to its identification number.

Now, let's key into the machine the program in Table 1.

The formula turns out to be somewhat an unwieldy one to use, as who of us uses capacitance values in farads. In step 008 the machine is told to convert farads to microfarads by going automatically into scientific notation when "EE" is pressed, and then in step 009 and 010 we enter into the program, the minus 6th power of ten. This allows us, when entering the problem's values, to enter capacitance values in microfarads and let the machine convert it to farads. Further into the program we round off our answer to two places beyond the decimal point. This is done in step 033 where we fix the number of places after the decimal point to two in step 034. If we feel that we really don't need any portion of an Ohm in the final answer, step 034 could be keyed Ø instead and the machine will then round off the answer to no places to the right of the decimal. Later, in steps 040 and 041, we tell the machine to go back to its original 10 digit display and clear all memories for a complete new set of values. Isn't that beautiful?

Let's do a sample problem and watch this wondrous little gem go through its tricks. Let's suppose that we have discovered that upon

end of program

Table 1.

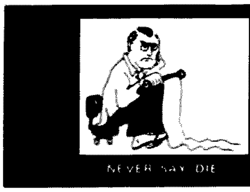
attempting to pipe a touch-tone™ pad into our phase modulator and bypass all the mic stages, we still can't key up that autopatch down the road.

Hmmmm ... the lowest frequency used in the touch-tone pad is 697 Hz, but the guys on the frequency all seem to agree that the high frequency tone is there, but the low frequency tone is very low in amplitude. Upon examination of the schematic we find that the coupling capacitor out of the inter-stage transformer in the mic circuit feeding the phase modulator is only an .02 uF.

Well, let's see ... picking up our trusty SR-52 and loading up the program, we enter the audio frequency value 697 into "A" and the coupling capacitor value .02 uF into "B". Depressing "C" tells us that the capacitive reactance of that .02 uF coupling capacitor is 11417.14 Ohms.

Gee, no wonder those guys on the autopatch can't hear the low frequency tone. Suppose we increase the capacitor value to .05 uF. What's the Xc value then? Returning to our miracle of miracles, we enter into "B" the new value .05 and once again press "C". Out spits 4566.86. Well, that's better, but not really good enough for the autopatch operation, so we try another capacitor value of .33 uF into the computer and out spits 691.95. I'll bet that works. Suddenly, after changing the capacitor to the new value of .33 uF, we find the autopatch swallowing our signal and keying up the dial tone.

If you have followed me through this exercise, you will now begin to appreciate this beautiful little handful of plastic and electrons. Loading some of the other programs that come with the instrument will truly open your eyes to the reason I, for one, will never be without my wondrous mental crutch. ■



...de W2NSD/1

NEVER SAY DIE

EDITORIAL BY WAYNE GREEN

from page 190

and on for much of my life, it wouldn't have been much trouble to get a W1NSD call back when the getting was good. Goofed.

The current frenzy over two letter calls is fun. When I suggested to the FCC that they offer special calls as an incentive to get an Extra class license (in 1963), they said that hams identified with their calls and would never go for it. Instead, they opted to punish hams for not upgrading their licenses rather than offering an incentive such as a special call. They called it "incentive licensing."

At any rate, while most of us were tied to our calls, a few found ways around the red tape. The ones involved in the conviction of the FCC chap were K8MM, K8KD, K8RS, and K8RZ, all of which now appear to have been withdrawn. All Ohio boys ... odd, since the last I heard, Ohio wasn't yet officially one the United States. They really should be issuing their own calls out there and stop voting in our elections. But that's another story, and an interesting one. It seems the Ohio legislature never actually got around to ratifying the joining of the Union, and by the time this was discovered, everyone felt it was better to shut up and not make waves.

Getting back to those licenses ... I have noticed others have managed to get counterpart calls, while I'm still living out the remainder of my existence as W2NSD instead of W1NSD.

The newspaper article made a big deal out of one of the FCC officials getting his own initials for his call. Big deal. The FCC's answer to that was that they tried to make officials more visible when they operated. That's not a bad answer. Perhaps something even more visible ... like W3A ... would have been even more satisfactory. Those one letter calls do stand out!

THE NEW "REPEATER" BAND

Apparently there are a few amateurs who have noticed that while the FCC deregulated the 144.5-145.5 MHz band so repeaters could be used there, the FCC made no mention that repeaters *had* to be used there.

With only a small percentage of the currently operational repeaters being used much, it seems counterproductive (dumb?) to start allocating a whole new bunch of channels for repeaters. Yes, I know that every red-blooded ham will not be happy until he has found out how difficult it is to set up and run a repeater of his own. Yes, I know that few of us are able to learn from the experiences of others and that most of us prefer to make our own mistakes, no matter the expense in time and money.

As the past setter-upper and maintainer of some repeaters, I can testify as to the trouble and expense. As a matter of fact, I suppose I should write up some of the adventures in repeatering as a humor article for *73* — the wading through four feet of snow to get to a locked-up repeater — the two snowmobiles in the barn just to get to the repeater site — all so a small group of misfits who had been chased off every other repeater in New England would have a place to spend the remaining days of their unproductive lives.

Should I mention the purchase of the duplexer? It seems that when you use a duplexer there is a little problem which gets kind of glossed over in the literature ... temperature. Temperature is something of which there is a great lack on top of a New Hampshire mountain during the winter. So this chap (a *73* staffer), who shall have to go unnamed, figured out a fix for that problem ... he set up a heater near the duplexer and I just about had heart failure when the electric bill came the next spring ... $350 to heat that damned duplexer. Let me know if you want to buy a duplexer cheap ... very cheap. I gave away the repeater.

So, do we need a whole new raft of unused repeaters in the newly deregulated MHz, complete with the usual wars between SSBers, CW DXers, AMers, and all the groups who have already announced that they are ready and willing to go to war? Why is it that the very first reaction to any change is to threaten war? I get the feeling that a lot of hams are excited over the prospects of getting back to war ... it's more fun. Cooperation has led to very dull repeaters and a big loss of interest. Now, a good hot war ... ?

Well, you do what you like. I really don't care if the repeater fans (and I'm one) have terrible battles over whether to go 20 kHz splits, or 30 kHz with 15 kHz unusable splinters (who *ever* learns from experience?). And I'll cheer on the sidewinders and their forays against the terrible repeater groups ... and the AMers leaping out to do battle with any repeater which dares to set foot inside the new band ... etc.

If people want to be foolish and waste their time and energy fighting instead of inventing and pioneering and trying to move things ahead, I'll do what I can to ignore them. It's a pity ... just think of all the new things we could develop if we would spend our time in a positive manner. We could develop some fantastic repeater systems — with automatic calling and message handling — with microcomputer interface — perhaps as an adjunct to burglar, fire, water, etc., alarm systems in hams' houses — tied in with ELT for locating planes which are down ... etc.

Just why the FCC didn't open the rest of two meters to Techs is one of those mysteries. Frankly, I think that was dumb. If the lack of a full MHz hasn't forced Techs to get a General license in all these years, why will the lack of a half meg do it?

WARC PROPOSALS

A reader sent along a copy of some of the foreign proposals for band changes which might interest you ... particularly if you have been worrying about whether to buy a new rig now or wait for one which will include those promised new ham bands which we will be getting after the ITU meeting in 1979.

The BBC proposals (remember, that is the British government) are to resolve the sharing of the 7100-7300 kHz broadcast band with amateurs by re-allocation (moving out the amateurs). They further point out that it is necessary to at least double each of the shortwave broadcasting bands below 20 MHz. Guess whose bands would be affected?

The BBC also wants to use up most of the ham 220 MHz band with added television allocations ... up to at least 223 MHz. Whoops, there goes 220!

The BBC will not have things all their own way with this TV plan, for the C.E.P.T. (Central Europe governments) wants to allocate 174-235 MHz for mobile service. They also are proposing 41-68 MHz for mobile (there goes six meters!) and a mobile service in the 430-432 and 438-440 MHz bands, replacing amateur use of those bands. These decisions were reached at a meeting in Puerto de la Cruz in 1974 and revised at Malaga-Torremolinos in 1975. They will probably stick.

Obviously we may lose more than just our low bands at WARC.

Boost Your TR22!

-- with a mini rock crusher

Larry Levy WA2INM
1114 E. 18th St.
Brooklyn NY 11230

My TR22 is a very nice rig, but it is a little short on the power output side to reach some of the more distant repeaters full quieting. There have been several modifications published that would increase the power output of this rig, but they all have common drawbacks: 1) There is barely enough drive for the final that is in there now, so the drivers have to be reworked to give more power. 2) The increased power means increased battery drain for the times that I want to use it on battery power. And, 3) the increased power doesn't help my other HT, when I want to use that at the QTH or mobile.

The easiest and most flexible solution is to build an outboard power amp, which will connect to either HT and can be used in the car as well as the house. (Actually, given the price and effort to build these, you could build an extra and leave it in the car.) The cost for construction is under $15, and it takes less than an hour to build.

Depending upon the transistor used and the rig driving it, you will get 9 or 10 Watts out with a 2N5590. If you have a higher-powered HT or base rig, you could substitute a 2N6081 (1.5-2 W drive, 15 W out), a 2N6082 (3-5 W drive, 25 W out), or a 2N6083 (30 W out), or, if you have 7-10 W available, you might try a 2N6084 (40 W out) or 2N6097 (40 W).

These would all use the same basic amplifier circuit. The 2N5590 and most of the others listed are available from CeCo Communications, 2115 Avenue X, Brooklyn NY 11235 (a *73* advertiser), and are reasonably priced (the 2N5590 is about $6, the 2N6081 is about $7, currently, and the others are comparably priced).

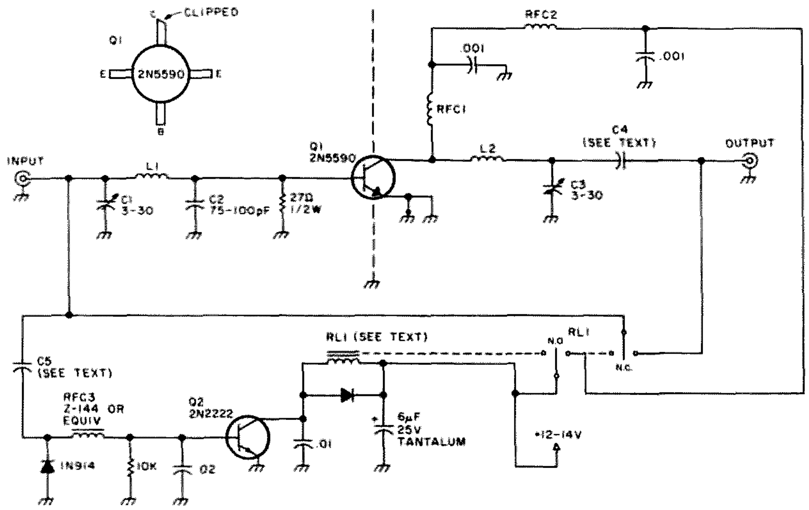

Fig. 1.

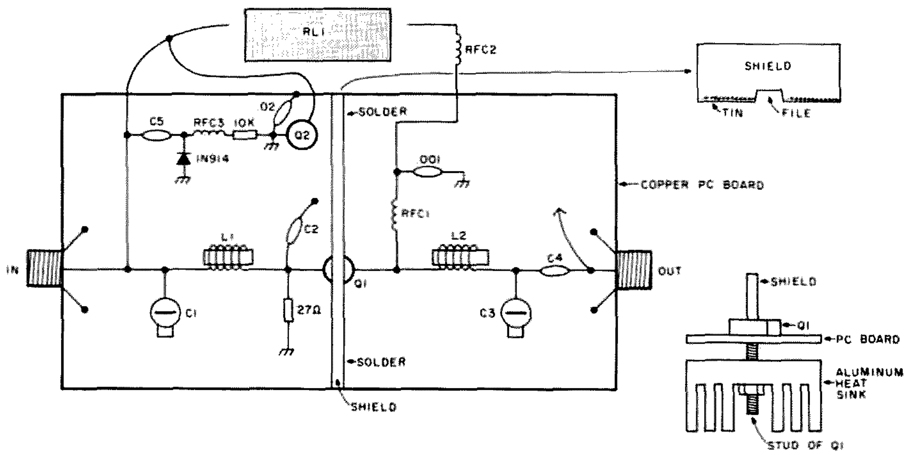

Fig. 2. L1 — 2½ turns #22 solid wire; L2 — same as L1, ¼" diameter spaced ¾"; RFC1-2 — approximately 6 turns #22 solid wire (insulated), ¼" diameter close spaced.

Construction

The amplifier is constructed on a piece of copper PC board, mounted on a finned aluminum heat sink. The stud of Q1 is used to mount the board to the heat sink. A scrap piece of PC board is filed to clear the case of Q1, and soldered to the

main board after the transistor is mounted and the emitter tabs are soldered to the main board. This acts as a shield between the input and output circuits. Layout is simple (see Fig. 2) straight-line construction. RL1 is a DPDT 12 V relay, with 25-50 mA coil current. (A relay with a higher coil current could be used, but the 2N2222 type transistor should be replaced with one having a higher current rating. The cheap plastic TO-220 type audio transistors should work fine for this application.) Radio Shack stocks a relay with the right current, available for a few dollars.

L1 and L2 should be dipped, with a few feet of coax connected. C4 can be a disc ceramic, about 40 pF. If really fine tuning is desired, it could be replaced with a 50 or 60 pF trimmer. C5 is a 1.5-7 pF trimmer. It could be replaced with a fixed value cap, if desired. 2-3 pF should work for a small hand-held HT or TR22 (1-2 W range), or a gimmick could be used for the higher power rigs (when used with the higher power transistors). In either case, the minimum capacitance that will give reliable keying should be used.

Tune-up/Operation

Connect the amplifier to a power source, and connect a wattmeter to the output with a dummy load. Tune C1 and C3 (also C4, if variable) for maximum output. Now back down C5 until the relay drops out, and increase it slightly until it keys reliably.

You might now connect the wattmeter to the input and check swr. C2 may be varied to get the lowest swr (with retuning C1), if the swr is high. Connect the wattmeter to the output, connect an antenna, and repeak for maximum. This completes the tune-up. A switch may be added in the power lead, so the booster may be shut off if not needed. ■

QRM on the Moon?

-- yep, on all bands

A while back, I had occasion to do some design work to determine the best frequency to be used by an explorer using a handie-talkie on the moon's surface. In that work, I had to calculate the signal levels arriving on the moon from all known Earth transmitters, to determine which frequencies were so QRMed that they would be a bad choice. The results were quite interesting in that they showed that most frequencies are already "occupied" on the moon by Earth QRM.

It may surprise you kilowatters to learn that your idle chatter bombards the moon with readable signal levels. If there had been moon people, they would have had little problem knowing all about Earthlings, since they could have merely turned on their radios and TV sets to monitor just about any station in the world broadcasting on frequencies above the broadcast band. Many persons will kind of suspect that TV signals with their 1 megawatt effective radiated power (ERP) might reach the moon, but few hams whom I have talked to even suspected that their QSOs regularly reached the moon.

Ham signals above 80 meters frequently reach the moon at enough strength to be quite readable, if a receiver up there using a decent antenna was tuned to the frequency. Most moderately powered transmitters that use dipoles, which radiate appreciable power straight up, reach the moon when it is high in the sky, providing the ionospheric critical frequency is low enough relative to the transmitting frequency to permit the signals to punch through at high radiation angles.

For those hams that may be rusty on their critical frequencies, Fig. 1 gives a typical summer and winter curve showing how these vary versus local time. In using this chart, remember that 12:00 local time is high noon by the sun, regardless of what your clock may indicate. Study of Fig. 1 reveals that the 40 meter signals punch through all the time except for a couple of hours each noon in the winter. Eighty meters punches through only late at night through early morning, and bands above 40 punch through always.

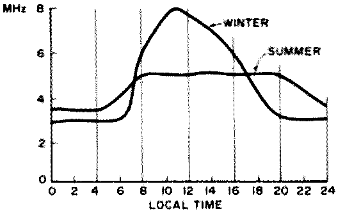

Fig. 1. Typical critical frequencies.

To show the signal levels arriving on the moon, Fig. 2 presents their level when the transmitter is 1 kW, and both the Earth transmitter and the moon receiver use ordinary dipole antennas. Notice that even on the moon one cannot escape static completely, since the galactic noise still prevails much stronger than pure receiver noise. The lower sloping curve on Fig. 2 shows the value of galactic noise versus frequency. To estimate the quality of signals reaching the moon, for example on 40 meters, consult the chart at 40m and read the received signal level as being -97 dB below a milliwatt (dBm). The galactic noise at 40m is about -107 dBm, so the signal to noise ratio will be about 10 dB in a 2 kHz SSB bandwidth, which is the bandwidth the chart is designed for. This 10 dB is not a very hot signal, but it is readable.

If antennas with vertical gain were being used instead of free space dipoles, such as, for instance, ordinary dipoles within a quarter wave of ground, a larger signal would prevail. For example, if a Super Gain[1] antenna was used on each end of the link, 14 dB more gain would result, giving a 24 dB signal to noise ratio, which is quite readable indeed. CW fans may rejoice in the fact that CW truly booms into the moon. This is because the human ear is equivalent to a 50 Hz effective pre-detection bandwidth, when using a receiver with a product detector. Therefore, CW has a bandwidth compression factor of 2000/50, or about 40 times, which amounts to 16 dB more signal to noise ratio over SSB voice. Thus, even a 100 Watt rig is very readable on the moon if CW is used.

Of course, there will still be the usual QRM from other hams on the same frequency, even on the moon. However, since beams and vertical antennas put very little signal straight up, those with such antennas will not QRM the moon, and the net result will be much less congestion on the moon.

The above values of signal levels are given in dBm, which are very familiar to all who do serious work in communications, but dBm may be unfamiliar to many hams whose usual jargon references signals in the notorious S meter system. I cannot convert to S values, since each receiver is different in its indication of S level, and gross differences even exist between similar units on a production run. However, the value of -97 dBm represents

[1] See *73*, Oct., 1970, pg. 8 for description.

3.8 uV in a 50 Ohm line. You will have to calibrate your receiver to determine what that would be in S units on your rig. Anyhow, this is a piddling signal for anyone who would try to communicate on Earth. Earth static and QRM are severe, and would completely mask such a weak signal. However, on the moon, such a signal, small though it is, would be above the noise and static far enough for useful communications.

So, you guys on the UFO net, be advised that the moon is listening, and one would be unwise to bad-mouth saucers, for this might offend some compulsive young saucer captain who may use his laser to ionize a conducting path between the nearest ripe thunderhead and your antenna, thereby delivering a bolt directly into the shack creating much smoke, reverence, and no doubt setting some record for the shortest though loudest digital message ever sent. Also, those who would like a temporary respite from our unresolvable terrestrial problems may want to contemplate what callsign the first moon DX expedition should have. ■

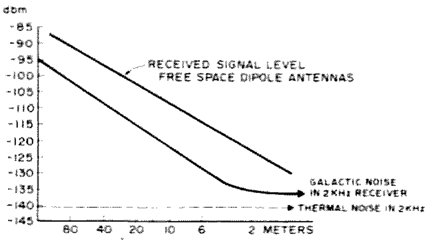

Fig. 2. Received signal levels on the moon in typical SSB receiver.

Filcher Foiler Car Alarm

-- car door operated

I have been a VHF enthusiast from the time I first knew of the 2m band, and I prefer mobile work most of all. This was to my advantage while in the Navy, as I could take my QTH with me wherever I might be stationed.

Now that I am a civilian, I decided to become more active and help save some of our frequencies. In Montana we had a great group on "two" but nowhere else in the VHF range. So, joined by another ham, I decided to do some work on 450 MHz. Since I own an IC-230, I fell in love with the IC-30a when I saw it. We both bought a unit at a great savings through the local dealer to help get our 450 effort off to a good start.

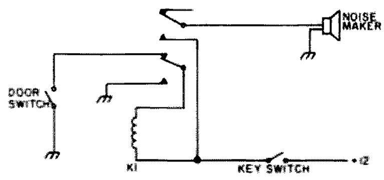
Since I owned a Pinto, I didn't really have the room for both rigs or two antennas, so I was always with one rig or the other. I soon tired of this ordeal (and decided to help the economy too) and bought myself a new Dodge van. Now this was big enough to hold my IC-230, IC-30a and my scanner, with enough roof to make the thing look like a porcupine. After weighing many options, I decided to make a shelf above the sun visors, since none of the rigs were more than two inches thick. I spent one whole weekend drilling holes, filing, sawing and having a great time. I then stood back and was pleased with what I saw. From left to right, the shelf was occupied by the IC-30a, the IC-230, the discriminator meter and, finally, the scanner. I still had plenty of room for a 6 meter or 220 rig in the future. I used the mounting hardware that came with the Icom gear. I put wood screws through the two holes in the clamps and affixed them to the shelf. I thought this way they were solid, but could be taken out if they ever failed (my first mistake).

Having never had any ham gear stolen, even in California, I didn't think about it. But I did always lock all the doors when I was away. Then I came out Saturday morning (one week later) to find my van raped and my IC-30a savagely ripped away from the shelf. The power and speaker cords were cut, but not the antenna, which had a slip on fitting since the SO-239 was metric. Once I got over the shock, I put out a QST (*A general call to hams, not a magazine. — Ed.*) on 2 meters to let them know what happened. In a daze, I then called the police and went through all the paperwork.

I made up my mind right then that this was not going to happen again. I called a few places inquiring about alarm systems. The prices varied from $80 to $150 for a complete job. I then gathered up my ham pride and decided I could build one for less money. After about ten minutes of head scratching, I came up with the circuit in Fig. 1. It is very simple and the total cost of parts came to about $25 to $30. All parts can be bought at Radio Shack except the door switches. They are the "dome light" type and must be bought at an auto parts store for about 79¢ each. If any door is opened the relay energizes and latches, putting plus battery to the noise maker. The only way to turn it off is to come to the vehicle and turn the key switch off. The relay I bought wasn't the best and needed some adjustment before it would quit buzzing and latch like it should. This part should be the best money can buy, as it's the heart of the system.

Since my van was new, it was a simple matter to install the door jam switches. Run all the wires to a common switch bus terminal, wire up the relay and mount the key switch. A mercury switch could be added so that if the vehicle is even bumped the alarm will go off. I now had a system ready to let me know if anyone got in. But how could I slow them down if they did get in?

The best way to come up with a solution is to think like a thief and figure out what would make it hard to take something. First, the nice mounting for the Icom gear had to go. I took the radio apart and found I had a lot of room inside near the front. So, I bought some "stove bolts" and drilled holes through the shelf and the bottom panel of the IC-230 case. With this bolted to the shelf, I put the radio back together around this bottom panel. This way, the thief would have to take the time to take the radio apart and, if he wanted the bottom panel, he would have to unbolt it. To do this, he would have to take the shelf down from the six flat iron brackets that hold it in place, with three screws through each of those. I did the same



with my discriminator meter, but my scanner was another problem. There wasn't any room for stove bolts, so I put four wood screws through the bottom panel into the shelf with huge washers (2 inches across) under the counter-sunk screw head. I then put the scanner back together around this bottom panel.

It took me a half an hour to assemble the radios onto the shelf and put the shelf back into the van. I am sure that if they want them badly enough there is a way, but my arrangement should certainly slow them down.

As someone once said, "an ounce of prevention is better than a pound of cure," so naturally I had the van insured for everything. I found out that I should get all but the $25 deductible back from my insurance company. I had had the IC-230 individually insured but hadn't yet done so for the IC-30a. If so, I would be getting the total value back. I found out from my agent that, with the measures I had taken, there was no question about insuring against theft with a blanket policy "covering everything that's in the van at the time." This is at about the same cost as the single policy I now have on the IC-230.

Since there are a few of us who would rather run these "rice box rigs" instead of commercial gear, and since the rigs look a lot like CB rigs, we must do what we can to keep these nice rigs from being borrowed by our "break in" brothers. I hope what I have done might help at least one fellow ham hold onto what he has saved for years to buy and enjoy. ■

Be sure to include a mercury switch attached to the hood if your vehicle's battery is accessible without entering the passenger compartment. Thieves have been known to clip battery leads to disable alarm systems. — Ed.

Quick Deviation Meter

-- for the IC-22A

Sooner or later a 2m FMer will find a need for a fairly reliable deviation meter. As is the case with most test gear, the cost of a commercially-prepared deviation meter doesn't make it a justifiable expense for the casual user.

However, being strong on need, yet weak in resources, an inexpensive deviation meter became a must for me. Going on the philosophy that a deviation meter is nothing more than a stable FM receiver with a visual readout, I took my trusty IC-22A and a VTVM and experimented. As a result, here's a quick and easy modification to an IC-22A which will allow for deviation measurement of other 2m FM transmitters.

Connect one end of a 9-inch length of #22 insulated wire to the junction of D2 and R43, located in the ratio detector circuit. Connect the other end of the wire to any open terminal on the accessory plug (Fig. 1).

Obtain, through any legitimate means, a VTVM with a 1 volt range and an rf probe (I used a Hewlett-Packard 410B and had excellent results). Attach the common lead to any ground point on the IC-22A. Plug the tip of the rf probe into the slot in the accessory plug which matches to the terminal now connected to the D2/R43 junction (Fig. 2). Turn on the IC-22A, and tune to any reasonably active frequency. Engage the squelch, so no noise is heard when no signal is present.

Now, turn on your VTVM, let it warm up, and set it for ac, 3 volt range. You'll notice that, when no signal is present, a fairly stable voltage of approximately 1.2 volts will be present. When an unmodulated signal is received, the voltage dips to roughly 0.8 volts. As modulation is applied to the signal, the voltage may then vary from approximately 0.8 to 1.0 volts.

In order to observe the variable voltage better, change the VTVM range control to its 1 volt position. Now, during a period of unmodulated signal input, adjust the meter setting to "0" or "center," whichever suits you best. As a result, when modulation is applied to the input signal, a meter movement following the pattern of the modulation will be observed. The observed modulation pattern will conform to the deviation of the input signal.

It is now necessary to compare meter readings to known deviations. I have found that on my IC-22A, utilizing a regulated 13.6 V dc supply, a peak deviation of 5 kHz will cause a peak voltage reading of 0.2 volts from my adjusted "0" setting. However, this may vary slightly on different IC-22As, depending on power supply stability, component accuracy, etc.

When using this quickie deviation meter, make sure that the input signal is not strong enough to desense the IC-22A. Also, be sure to measure deviation on a simplex frequency, not through a repeater. ■

Build a Noise-free Power Supply

-- avoid spikes with sine waves

I've been doing a lot of experimenting with miniature solid state receivers the last few years and in most cases have stuck with single 12 volt power supplies just in case I should want to use batteries at some time. Most of the ICs I use are designed for nominal 12 volt operation, and when a few op amps are sprinkled into the circuit, I generally offset the output to 6 volts by biasing the non-inverting input with a couple of resistors and ac coupling everything. This is common practice and in most cases quite satisfactory.

Then I became intrigued with the idea of using a PLL in one of my designs, but the NE561 needed at least 13 volts for satisfactory operation. Besides the PLL, I had several 741 op amps in the audio and agc circuits whose performance could be improved by the use of dual polarity supplies. An ac supply capable of providing 3 voltages was no problem, but battery operation would call for a converter of some kind.

In the past I've built my share of dc to dc converters using saturating cores and switching transistors, but it seemed I always had a terrible time taming these beasts. Tremendous spikes would show up on the output and cause all kinds of problems in the equipment being powered by this pulse generator. This time I decided to cut out the problem rather than try to cure it. Instead of the customary square waves, I thought I'd start with a pure sine wave and use an audio amplifier to build up the level to a value suitable for feeding into a power transformer.

The idea worked quite nicely and a schematic for the converter is shown in Fig. 1. The majority of the receiver circuits operated from 12 volts and were fed directly from the battery. The NE561 was run off the +15 output and the op amps from both outputs. My circuit drew about 5 mA from each output, but as much as 10 mA should be possible.

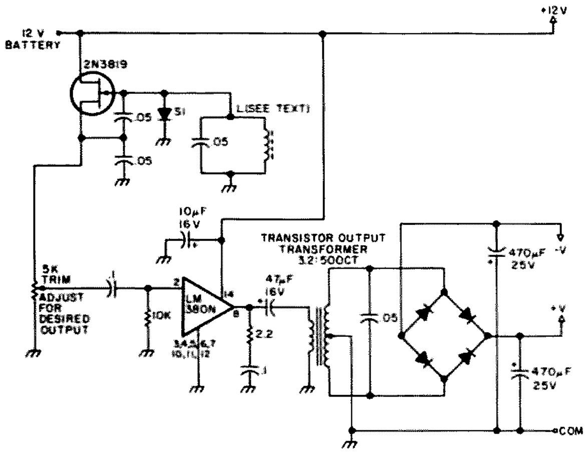

Fig. 1. Schematic for the spike-free power supply.

All kinds of chokes and transformers were tried in the oscillator tank circuit, but eventually it was found that a hand wound pot core inductor worked best. The pot cores I used were obsolete Ferroxcube parts, but similar units should work as well. Mine are about 3/8" in diameter and 5/16" thick with both halves assembled. Material is Ferroxcube 3C. The bobbin was wound with 800 turns of #44 magnet wire. On a homemade bridge, the inductance checked out around 700 millihenries. In the power supply the oscillator frequency is around 900 Hz.

An LM380N audio amplifier IC is used to drive the voice coil side of a standard 500 Ohm to 3.2 Ohm output transformer. I used Radio Shack #273-1379. The bridge rectifier is one of the small plastic units about the size of a TO-5 transistor case. The transformer center tap is grounded and the dual polarity voltages taken from either side of the bridge. Output level is set by the 5k vertical trimmer which controls drive to the LM380. This control should be set with the load connected. All decimal value capacitors are 50 volt discs and the rest are electrolytics. Resistors are ¼ Watt carbon. The silicon diode may be a 1N914 or any other type used for switching or general purposes. Other JFETs will work in most cases as the oscillator transistor. Just make sure you get the right pins in the right holes since not all packages have the same pinouts.

Tests made with ±15 volts out and 10 mA load on each supply showed a maximum ripple of 15 mV peak to peak. At 5 mA loads, the ripple dropped to 8 mV peak to peak. Input current from the 12 volt source was 85 mA and 55 mA respectively. This is not particularly good efficiency, but at these low levels it was of no great consequence. The 900 Hz hum was just about audible with the receiver quiet but normally was lost under background noise.

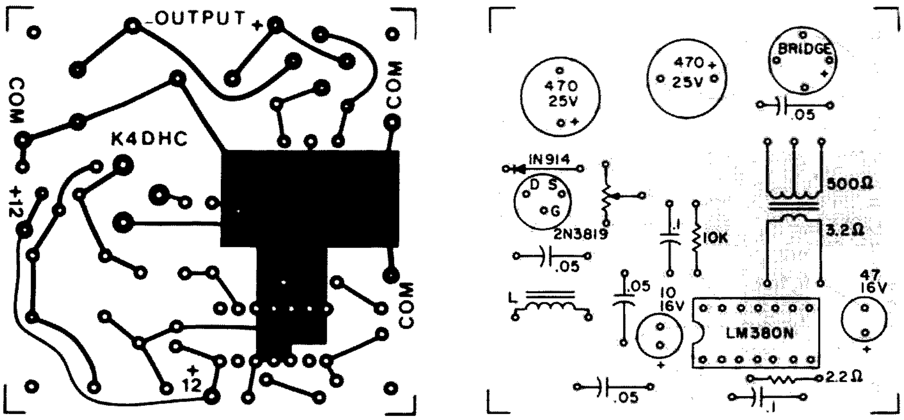

Fig. 2. PC board layout and parts location as viewed from copper side.

The PC board layout and parts placement are shown in Fig. 2. The board is 2.3" square. The pot core inductor was potted in a cylindrical form after winding and provided with 2 radial leads for insertion into the PC board. A finished inductor and undrilled board are available from me for $5 including postage. ■

San Antonio TX 78209

Surplus Goodies

- - are they really for you?

The question of whether or not government surplus is for the Novice deserves a simple answer, but an unqualified answer cannot be given. It resembles the question, "Should you build or buy?" The answer depends on the ability of the Novice. Generally, the surplus market is not for the Novice. The best advice is to look, but don't buy. It sounds easy, but surplus is sometimes difficult to leave alone. Many of the new units can't be utilized in their present forms, but they look so pretty that it is normally assumed a useful conversion is possible.

Leave it alone. Especially if you do not have the loot to play with. If you are lucky enough to become a Novice already possessing the knowledge and skills of an electronic technician, the value of the surplus will be apparent.

Another deterrent to buying government surplus is the new Novice regulations governing power and frequency control. Two hundred fifty Watts is unusual in military equipment. Most units are rated much lower in their outputs and are seldom worth the money if any thought is given to upgrading your license in the future. Yet the outlay of several hundred dollars to obtain one of the late model transceivers is not the wisest of moves if you consider the possibility of losing interest in amateur radio before advancing to a higher stage in the license process.

Assuming the interest is there but the money isn't, at least one surplus buy may be in order: a receiver. Check the bank account and see if you have ten or fifteen dollars that can be used for a trip to the nearest surplus or junk dealer that has government surplus materials in stock. Do not be influenced by the prices advertised by the many mail-order houses that dwell on the misinformed nontechnical Novice. Keep in mind that you can spend a bunch of green for a great receiver that will provide features you won't find anyplace else. I would recommend that you do so if it's affordable. There are many available at any price you would like to pay.

One of the most important steps to take before visiting the local surplus house or yard is to familiarize yourself with surplus equipment that has been used in amateur service during the past thirty years. Careful scanning of the catalogs issued by several of the surplus mail-order houses and, if they are available, old copies of various ham magazines can supply a great deal of information. There are a few units still available from World War II that require very little, if any, conversion.

A recent trip to the local surplus dealer to buy a piece of angle iron for a certain project turned up something more and is a common occurrence. Digging through towering piles of so-called junk left out in the weather, I found several old BC 342 receivers and ARR 7 receivers. The covers were in bad shape . . . paint flaking, mildew, and other indignations that had been thrust upon them by the years of bad weather and the rough handling that is apparent in a junk yard. Producing one of the small screwdrivers that I normally carry on my salvage trips, I had one of the receivers open in a flash. Everything was intact and spotless on the inside. The junker wanted ten bucks for the four receivers, two BC 342s and two ARR 7s. I offered him five and he settled on six if I took them all. I did.

The BC 342 is a big piece of reliable iron with tubes. It lacks many refinements but it will get you to 18 MHz, just short of 15 meters. It is better used as a general coverage radio, although many have been used in amateur service. It is one of the few that will operate unconverted.

The ARR 7 is a military version of the old Hallicrafters SX-28 modified to conform with most aircraft equipment of World War II. All the controls were moved to the end of the chassis so that the radio could be inserted lengthwise into the aircraft. The addition of an audio output transformer, a power supply, and a couple of wiring changes can provide an excellent and inexpensive way to listen in on all the activity from the broadcast band to above ten meters (.55-42 MHz). There have been later models but, as with most equipment, the price goes up along with the later release date. And sometimes it isn't as good in quality.

These are just two examples of what you can find if you do a little digging.

If you are like most who develop an interest in amateur radio, one of the first events that takes place is making friends with that guy down the street who has the wires hanging all over his house. If he is a do-it-yourselfer, you will learn something from him and he can give you a big assist in buying, building, or modifying existing equipment.

Besides a telegraph key, you can pick up a low power surplus transmitter that will perform satisfactorily. Contrary to the "power mongers" that are graduating from the CB ranks (if the shoe fits), it really isn't necessary for Novice operators to have a large transmitter output. The increase from a maximum 75 to 250 Watts input was

apparently an attempt at appeasing manufacturers of equipment under the guise of providing an "extra" for the Novice. If the main interest is learning and increasing code speed, power isn't going to help. Fifty Watts more or less will do the job. There are many used commercial models selling for twenty or thirty dollars. Some for less. Most of these are crystal-controlled, which is the biggest drawback. A VFO (variable frequency oscillator) which allows the operator to dial the transmitting frequency is probably the one late improvement that nullifies the increase in power. If your signal is covered by a stronger station, a simple twist of the wrist and you can transmit somewhere else on the band.

With the addition of a transmitter, the one item that remains is an antenna. Several things will determine what your antenna requirements will be. The length of an eighty meter dipole in most cases makes it a difficult antenna to install. Since the main objective is to keep the cost down, the most logical is a dipole. Not only will this be less expensive, but also the results that are obtained are more satisfying. The problems involved are mainly with the area needed to install a piece of wire in the length required. If you intend to operate at night only, then you can eliminate the possibility of ten and fifteen meters and concentrate on putting up a little over sixty feet of wire. I personally preferred fifteen meters due to lack of noise, less crowds, and less room needed for the antenna. Regardless of which band you choose, you still have to have the antenna.

A unit that has been on the surplus market for years and is now obsolete contains the ingredients plus quite a few little odds and ends that you can have fun with. The old CRT-3 (Gibson Girl) survival radio transmitter can be found in almost any junk yard. If you don't know what one looks like, and you missed seeing Robert Taylor use one in the World War II movie, "Bataan," I shall try to describe one. In kit form it comes in a canvas bag with a lot of accessories: balloons, kite, hydrogen generators, telegrapher's key, parachute material, and antennas. Usually the transmitter is found without the accessories, and can be bought as scrap metal. It has a kidney shape with a folded handcrank. There is a door on the front case that contains a fully prepared reel of stranded copper wire. If it is a junk unit, the reel is easily removed. It may cost you two or three dollars at the most.

Any other "buys" of surplus gear would be a waste of money. Many of the items carried by the surplus dealers are truly bargains, but not for the Novice. Some test equipment and other units can save you a bunch of money at a later time when knowledge and experience overtake the desire to proceed to higher goals in amateur radio. This not only applies to the Novice, but also to the older group that is presently migrating into amateur radio.

With the equipment listed or other government surplus units, you can get on the air inexpensively and find out if amateur radio is really for you. There are many ways to equip the Novice station. This has been but one. There are other pieces of surplus that can be utilized without conversion, but the price eliminates the equipment from the bargain category.

The simplest method is to avoid surplus as a Novice. It will save you time and money. ■

Author's note: The December, 1962, issue of *73* featured a conversion article by James M. Stueber W5UOZ. It's one of the most complete ARR 7 conversions available.

Try A New Mode!

-- don't let boredom strike

I know exactly how it was. You snatched that Gettysburg-postmarked envelope out of the postman's hand, not even giving him a chance to give you the bills and junk mail, lit a streak down the basement steps, and had the filaments warming up while you tore into the thing. And there it was – your own amateur license, complete with totally unpronounceable call letters, indecipherable signature, and of a size so it wouldn't fit your wallet, no matter how you folded it. In short, it was beautiful!

Then you made that first contact, hand jerking spasmodically on the key, sweat dripping off the end of your nose onto the logbook. And from there, you fell deeper and deeper into the euphoria of amateur radio.

It could be now, though, that you've cooled down a bit. Call it the sophomore slump, the child-and-his-new-toy syndrome, or whatever, but you've reached a point where you don't really want to talk about the weather with that guy in California or get another 579 from New Jersey. You find "Starsky and Hutch" more interesting than a dead fifteen meter band. And when the ice storm gets your dipole, you keep forgetting to put it back up.

Recognize your symptoms?

There are two ways you can go now. Sit there, molting, and let your hobby, rig, and license go down the tubes. Or use a little imagination, inject some excitement back into amateur radio, and have the time of your life – even more fun than when you tore into that envelope from Gettysburg.

I'll bet we've all heard about the fellows who dropped out, letting their licenses lapse, blaming it on "twenty meters went to the dogs," or "I couldn't get my code up for the General," or "I was just so busy down at the office." With lame excuses like that, no wonder they couldn't muster up any imaginative ways to get some life back into their hobby.

If you will just stop to think about it, you can probably come up with many ways to perk up your enthusiasm, and most of them can be accomplished sitting right there in front of the rig. Can't think of any? Read on!

Have you ever checked into a traffic net or relayed a message from a homesick serviceman back home to his folks? One of the biggest thrills you can have is to hear a tearful mother's voice on the telephone thanking you for letting her know her son or daughter has survived an earthquake. I know from personal experience what satisfaction it is to allow a missionary in a remote South American jungle speak with his family back home. The day-to-day handling of formal messages on the ham bands involves hundreds of amateurs in a valuable public service activity.

You can find the nets in your area by listening or by sending a self-addressed, stamped envelope, 6" x 9" or larger, to the American Radio Relay League, requesting the net directory. The procedures used can be quickly learned by listening or by reading several ARRL publications which are available. There are also many slow speed or Novice nets, which offer a great introduction to traffic handling (and some super code practice, too).

Phone patching requires listening and volunteering when appropriate (and, of course, a patch!). The Military Affiliate Radio System (MARS) offers many a chance to perform a public service.

There are also plenty of special interest nets and round tables. Some specialize in assisting mobile operators, relaying traffic to missionary personnel or to ships at sea. Some are for physicians to assist in medical problems in remote areas. Whether you're interested in politics, religion, parapsychology, ecology, or a technical discussion, you can find somebody with similar interests, either by simply listening, or by watching for blurbs in the radio magazines. You might even send one in yourself. There are even professional group nets, such as attorneys, post office employees, and the like, who get on the air, not to just talk shop, but to share similar interests and experiences.

Like to play a little chess? There are many games and activities which lend themselves well to amateur radio. It may be a simple game of checkers or the complexity of "Diplomacy." You may practice your stamp collecting or discuss computer science. Practically any other hobby you enjoy can be combined with amateur radio, with the enjoyment multiplied.

Have you thought about experimenting with other modes? RTTY, slow scan or fast scan television, OSCAR, or even CW – all exotic life forms for engineers? Hardly! They are proving to be loads of fun for thousands of us who once thought we could never get the hang of such way-out weirdness. Expensive? Not necessarily. Build,

find used gear, scrounge around – getting there is half the fun. And wait until you see that first SSTV picture from the Middle East or good teletype copy from a station in Japan. There are plenty of books available for the beginner in each of these specialized modes, and you will find that most people already involved like nothing better than to talk about their interests and will be glad to help a newcomer.

And though you probably worked pretty hard to get away from that 5 Watt limitation on the Citizens Band, you are missing a lot of challenging fun if you don't give QRP a try. Several QRP rigs have been featured in the various magazines, and more are available commercially. Sure, it can be frustrating fighting the full gallons with flea power, but when that fellow in Germany gives you a 589 and refuses to believe your 3 Watts input, then you'll know true happiness. QRP is sneaky, too, in that it makes you a better, smarter operator and forces you to learn a little about antennas and propagation.

There are a lot of things you can do off the air to get the fun back into your hobby.

You say you haven't built anything since the code practice oscillator when you were working on 5 words per minute? There are plenty of projects that are not only fun to build, but also are so useful you'll wonder how you ever did without them. Parts are as reasonable now as I can ever remember, with a friendly electronics store on practically every corner. There is no better way to get a firm grasp on the modern technology than to hook some of those funny little things together and see what happens. Even if you only thought a soldering iron was good for burning holes in the carpet, there are kits available that you can put together, get a good idea of how it all works, and have a good piece of gear when you're finished. I have a friend who tries to start a new project every week. He has never finished one, but he has a ball.

You may get out of the house and join a local club. Very few hams bite, and most are friendly sorts. And your club most likely has interesting programs and speakers, worthwhile fun projects, and maybe even coffee and doughnuts. There is also great satisfaction in participating in club projects, like public service activities, helping plan a hamfest, or presenting a program yourself.

I don't know how you got started, but a lot of us attended formal classes. And classes like that need instructors. You? Sure, you can teach! Or maybe set up chairs in the classroom, work on publicizing the classes, or just help passing out books. Or you could do something on a smaller scale, like helping an interested prospect in the neighborhood or teaching a scout troop.

As long as you're volunteering, raise your hand for the work party at the repeater site. It's a great way to get to know the locals, learn a little about VHF by doing it, and do a little toward keeping the machine going. And you could also take part in the next disaster drill, too, or maybe help with communications for the motorcycle races, or man the information booth at the shopping center, or accept an operating assignment for Field Day, or demonstrate the rig for a school science class. You get the idea.

Then, you could even sit down and write an article about some of your projects for *73 Magazine*.

And then, if you can possibly find the time, you could sit down at the rig and have a good old-fashioned rag chew. ■

73 Magazine *Staff*

Build A Useful HF Receiver

-- Novice special

It is interesting to note how events sometimes go around full circle in the amateur radio field. Many years ago, the only way to have an amateur band receiver was to build one yourself. Then later on, as commercial equipment appeared, most amateurs regarded those who "rolled" their own receivers as a group of technical geniuses. Building a transmitter wasn't too difficult, but building a good receiver was another matter. A crude, crystal-controlled transmitter with plug-in coils could be built with a minimum of electrical/mechanical workshop facilities. But to build a good receiver required good test gear and practically machine shop facilities.

Today, with solid state components and PC layout technique, almost any amateur can build a receiver with performance matching commercial units. For those who would like to start to try their hand at receiver building, this article presents a simple HF utility type receiver. It can be used to monitor WWV, to check specific frequencies in the HF bands, or to monitor station transmissions.

As presented, it is crystal-controlled, although one could add a vfo for continuous tuning of its entire range or of just specific bands. With the addition of an audio-type CW filter, it would make an excellent little receiver for portable QRP operation.

The receiver is a single conversion, superheterodyne type, with an FET front end, and is crystal-controlled. No bandswitching is required when it is used over the 6-15 MHz range. Coil usage has been held to a minimum to simplify construction. Construction is also facilitated by the use of a single IC for all audio amplification and the use of a commercial i-f amplifier module.

The schematic for the receiver is shown in Fig. 1, as it would be used for WWV reception. Note that the only switching which has to be done to receive WWV on different frequencies is that necessary to select the appropriate local oscillator crystals. The frequency coverage can be extended below 6 MHz and above 15 MHz, by using a different coil between the MPF 102 (HEP 802) rf amplifier and mixer stages. Or, in the case of just extending coverage below 6 MHz, a 100-200 pF padding capacitor, across the 210 pF variable capacitor shown,

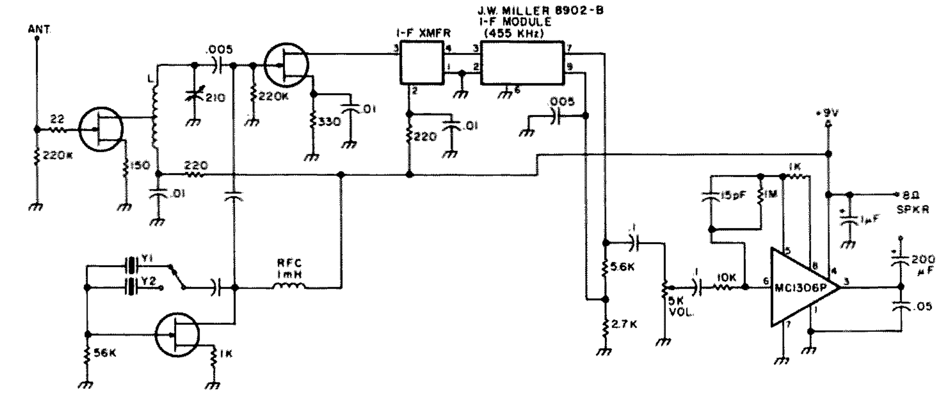

Fig. 1. Complete diagram of the receiver. All transistors are MPF 102 or HEP 802. The i-f transformer comes as part of the J. W. Miller i-f module. L = 26 turns #26 on ¼" form. Tap at 13 turns (for 6-15 MHz). Y1 = 9,545 kHz (10 MHz WWV). Y2 = 14,545 kHz (15 MHz WWV).

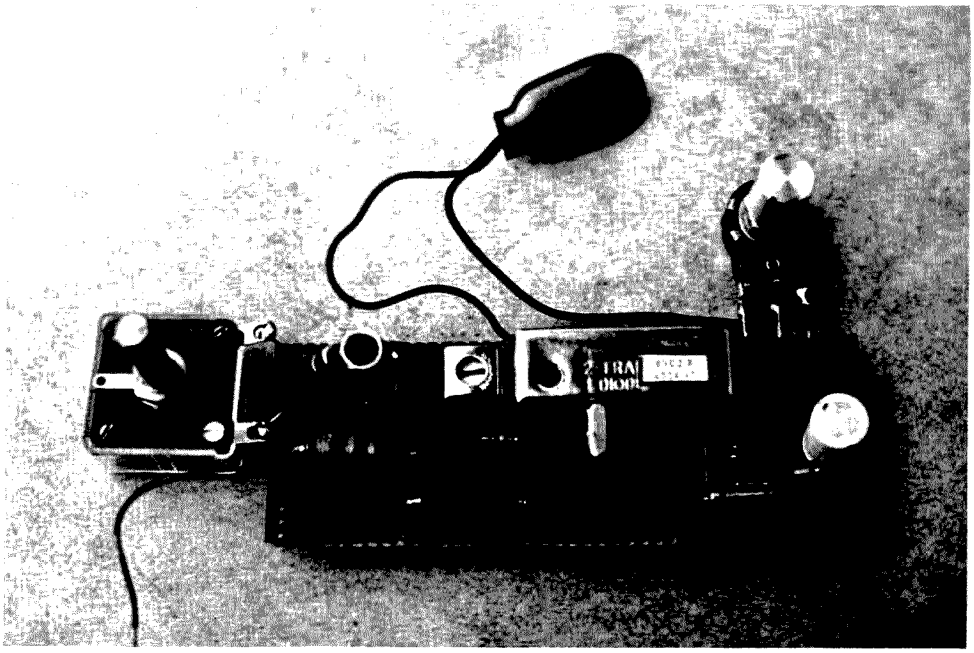
should extend coverage down to the 80 meter band.

The MPF 102 rf amplifier stage is untuned at its input. Its main purpose is to keep the antenna from loading down the tuned circuits between the rf amplifier and mixer stages. This single tuned circuit is sufficient to provide reasonable image rejection. The MPF 102 mixer stage and MPF 102 crystal oscillator stage are conventional. The oscillator stage is untuned. This has proven satisfactory for general reception, using regular miniature HC6/U type crystals. With some sluggish crystals, the rfc shown in this stage may have to be replaced with a tuned circuit.

The i-f amplifier module is a J. W. Miller type 8902-B. This module is just a two-stage i-f amplifier, complete with all necessary i-f transformers, and it also includes an AM diode detector. Its use greatly simplifies construction. If one can't find it readily available, a simple substitute is to cannibalize the i-f section from a small transistor portable radio. But, use an i-f section which has at least two stages. The really cheap $5 portables often use only a single i-f stage, and this will not provide sufficient gain for any sort of reasonably sensitive reception.

The audio amplifier IC is a Motorola MC1306P. This is a neat, inexpensive ($1) IC, which combines a preamplifier and ½ Watt output amplifier in one package. A minimum of external components are needed to make it function. If you did "borrow" the i-f strip from a cheap AM portable to build this receiver, *don't* be tempted to "borrow" the audio section of the AM portable, also. Generally, the quality of such audio sections is horrible, when compared with the clean sound of the MC1306P used with any small, but decent, 8 Ohm speaker.

The photo shows how the receiver was initially laid out



This is the complete receiver, as assembled on an approximately 4" x 2" piece of perforated board stock.

on a piece of perforated board stock. Simple point-to-point wiring was used. The layout wasn't planned, but, rather, construction started on a slightly larger piece of board stock. Starting with the rf amplifier stage, the components were simply grouped together as closely as possible, as I worked from left to right. The rf and mixer stages were grouped around the interstage coil. The crystal oscillator stage is below the i-f amplifier module, and the af amplifier IC is just to the left of the electrolytic capacitor, shown at the extreme right middle side of the board. When the receiver had been assembled, the oversize perforated board was carefully cut down to its final size.

The tuning capacitor used is a regular BC type and is temporarily shown attached at the left side of the board. The receiver should be mounted in a metal enclosure, and the ground leads used in the receiver should be carefully grounded to the enclosure at several points. Although the receiver did work fine wired as shown in the photo, it probably would be safer, from the viewpoint of avoiding possible spurious oscillations, to utilize an isolated pad type of component mounting/soldering technique. The relatively new Stamp-It, Etch-It kit, sold by Rainbow Electronics (see *73* ads), is a pretty handy way of developing an easy do-it-yourself PC layout for the receiver, if you like to take a bit more time but end up with a more professional-looking PC board.

To use the receiver to monitor SSB transmissions, a product detector and bfo have to be added. The circuit for a suitable product detector/bfo is shown in Fig. 2. It is relatively simple and inexpensive. If the product detector circuit is added to the receiver using the J. W. Miller i-f module, you have to remove the shield can from the module and take the i-f signal off the first 1N67A, *before* the diode detector is built into the module. This operation is fairly simple and obvious, if one uses the module, since a diagram comes with it, illustrating the modification. The diode AM detector need not be disconnected, however. So, one can, if desired, add a switch at the volume control to choose either the output of the product detector or the output of the AM diode detector.

With a mixture of some parts from one's junk box and newly-bought main components, the receiver can be constructed for about $20. This represents a rather modest cost for a utility-type HF receiver, for which one can find many applications around the shack or in portable use. ■

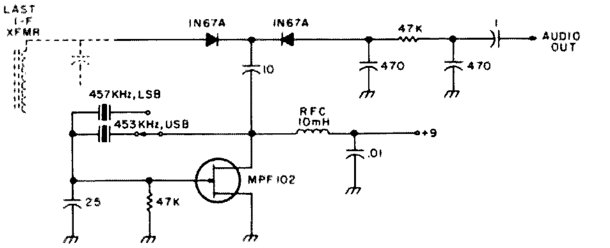


Fig. 2. Product detector/bfo, which can be added for SSB reception.

Wake Up A Dead Repeater!

-- with these new Q signals

Guy Slaughter K9AZG
753 W. Elizabeth Dr.
Crown Point IN 46307

Because the sophistication of state-of-the-art radio gear hasn't been matched by improved ham operating practices, it is often essential for an amateur to vent his spleen over the air in one or another of a patterned program of careful comments.

And no such comments, despite the need for their frequent repetition and the necessity of avoiding actual profanity, are the subjects of any of the "Q" signals on the traditional list.

I have developed, therefore, a suggested list of updated state-of-the-operating-art "Q" signals intended to lower the blood pressure and restore tranquillity without violating the FCC "no obscenities" regulation.

There undoubtedly will be others recommended by other hams.

My suggested list, therefore, is open to amendments, revisions, additions and modifications by fellow hams also frustrated by the shortcomings of other operators and the traditional list of "Q" signals.

Welcome to recommend such amendments or revisions are all who have within the past year sat in for even a few minutes on a DX contest, a sweepstakes, or a band opening to a rare call area.

Because the purpose of the proposed list is to help vent the emotions sure to be seething in the modern ham handicapped by others' operating techniques, most of the suggested "Q" signals are assertions, not the bland and polite question-and-response types of the outmoded traditional list.

They are most useful when delivered as commands or comments, with feeling. ■

QXA	Hey, dolt, tune up someplace else.
QXB	Drop dead, oaf, my dummy load is busted.
QXC	Quit calling through his comeback, jerky.
QXD	I gotta call long, because I'm running low power to a poor antenna with a lousy fist.
QXE	He's listening up two, but you'd better go down five.
QXF	Buzz off, buster. I got here first.
QXG	Slow down, finkie. Your dits sound like ignition noise.
QXH	Speed it up, nipsie. Code practice is over and the band is going out.
QXI	You're working the wrong street, friend. They only use AM on 27 now.
QXJ	Sign, for goodness sakes. I've been waiting 20 minutes to put your call in the log.
QXK	Quit calling through his comeback, dummies.
QXL	Don't expect a card, OM. I don't keep a log.
QXM	Don't gimme that exotic call from Illinois, Mac. I could care less about your state fair station.
QXN	Boy, you gotta lousy fist.
QXO	I worked him before, anyway.
QXP	That ain't hum on me. I'm just blocking your receiver.
QXQ	(Expletive deleted — this is the biggy, the quick tension releaser. It's bad, nasty and very helpful in a crisis. But it should be saved for true crises.)
QXR	I told you before, dang it — quit calling through the rare cat's comeback.
QXS	I copied you solid, 100 per cent, OM, but I can't remember what you said.
QXT	I'm not working for my Extra, cuz I don't believe in that incentive jazz.
QXU	All solid state here. Someday I'm gonna lift the lid and see what's inside.
QXV	I wish to QXQ you QXQers would quit calling through the rare guy's comeback.
QXW	Nil copy, cuz them QXQers keep calling through your comeback.
QXX	I'm reporting you blind, cuz them QXQers keep calling through your comeback.
QXY	I distinctly heard a "G," so I'm gonna put you in the log — even though them QXQers keep calling through your comeback.
QXZ	Where'd everybody go?

Social Events

HAZEL PARK MI
DEC 4

The Hazel Park Amateur Radio Club is holding their 12th annual Swap & Shop on December 4, 1977, at the Hazel Park High School. Admission is $1.00 at the door. Main prize tickets are available from Robert Numerick WB8ZPN, 23737 Couzens, Hazel Park MI 48030. Reserve table space is available from WB8ZPN.

NORTH POLE
DEC 6-17

The Calgary Amateur Radio Association is pleased to announce "Operation Santa Claus" will be activated again this year. Commencing December 6 until December 17 inclusive. CARA will be operating between 0200Z and 0300Z on 3790 kHz and between 0300Z and 0400Z on 3910 kHz. These frequencies are plus or minus QRM. At that time there will be two stations on frequency, a net control station and a Santa Claus station. All calls, from amateur stations with children wishing to speak to Saint Nick at the North Pole, will be accepted. Merry Christmas.

ROYAL OAK MI
JAN 8

The Oak Park Amateur Radio Club's Ninth Annual Swap n' Shop will be Sunday, January 8, 1978, at the Frost Junior High School in Oak Park (north of Nine Mile on Scotia). Talk-in on 52/52. Admission is $2 — ample table space. Hours are from 8 am to 3 pm. Prizes and refreshments. For further info, write to: Lee Ricelli WA8RNB, 118 South Pleasant, Royal Oak MI 48067.

SOUTH BEND IN
JAN 8

A Swap & Shop will be held January 8, 1978, at the New Century Center in downtown South Bend by river on U.S. 31 Oneway North across from St. Joseph Bank Building. Half acre in one large room at ground level of entrances and loading dock. Four lane highways to door from all directions. Talk in on 52-52 and area repeaters.

RICHMOND VA
JAN 15

The Richmond, Virginia, Winterfest will be held on January 15, 1978, at the Bon Air Community Center, sponsored by the Richmond Amateur Telecommunications Society. ARRL coordinated. Technical symposium, drawing, home brewers contest — 2 divisions, over 18 and under — with framed certificate to winners with Most Original Idea, Best Mechanical and Best Electrical Construction. FCC exams will be administered, starting at 10 am — to take exam, mail Form 610 at least five days prior to Fest to address below. Send SASE if you need Form 610. Commercial exhibits, indoor flea market, $2.00 (table included), outdoor frostbite tailgate flea market, $1.00. Admission $2, children under 12 free. RATS members excluded from contest and drawing. Talk-in on 28-88 and 52 simplex. Richmond Amateur Telecommunications Society, PO Box 1070, Richmond VA 23208.

FORT WAYNE IN
JAN 22

The annual Fort Wayne Winter Hamfest will be held on January 22 at Shiloh Hall, north of Fort Wayne, from 8 am until 4 pm local time. Early parking is available and 28/88 and 52/52 will be monitored. This yearly event is sponsored by the Allen County Amateur Radio Technical Society (AC/ARTS). Admission is $2.00 at the door. Table space is available at $1.50 per half table (about 4 feet).

ST JOSEPH MO
JAN 31-MAR 7

The Missouri Western State College Center for Continuing Education is offering a Novice amateur radio class on Monday evenings, 7 to 9 pm, January 31 through March 7, at the Engineering Tech. Bldg. 110. 6 meetings $5.

DAVENPORT IA
FEB 26

The Davenport Radio Amateur Club hamfest will be held on February 26, 1978, at the Masonic Temple in Davenport, Iowa. Admission is $2.00 advance, $2.50 at door. Talk-in will be on 28/88 and 52 simplex. Tables will be available at $2.00 each. For info and tickets, write: Dick Lane WAØGXC, 116 Park Avenue So., Eldridge IA 52748.

Ham Help

I'm asking the help of anyone who can help me get started on SSTV. Any help, information, and/or tips will be greatly appreciated.

Steve Ketler WA1WFA
85 Columbus Avenue
West Bridgewater MA 02379

I recently purchased a theater projection television system. The problem is that I need a picture tube and service information. The set is built by RCA, model PT-100. The picture tube is a 7NP4 or 7WP4. Neither the tube nor manual are available.

I realize that your magazine is mostly amateur radio, and while I am not yet a ham, I do have a 1st phone and repair commercial equipment for a living. I also service amateur gear as well. This TV system is not the small home-type that was popular years ago and is making a comeback. It is a huge commercial projection set that is often used to present fights and races in movie theaters. This unit is quite old, so there are no parts or info available today. It's a very impressive piece of gear, and I would love to make it work again. I never plan to use it commercially. I feel that some reader of your magazine might be able to help me get this monster going.

Bruce Gentry
624 Plymouth Ave.
Mattydale NY 13211

I am a reader of *73*, am not a ham (yet), but need help. The help I need is the answer to this question: Where can I buy a good, used "pan adapter" — that is, an oscilloscope device which visually displays all signals on a 300-500 kHz band? I would consider a new one, if it wouldn't cost the moon. My receiver is a National HRO 600. Any ideas?
